On August 9, 1940, examined the Cirac property near Aurora, Nevada. A number of assays taken by the Howe Sound Co show some gold and silver, and commercial values in copper. It has been reported that nickel and cobalt are also present. Only type samples were taken, as size of deposit did not permit a detailed examination in one day. Mineralized areas can be traced for a length of 4,500 feet and a width of 400 to 600 feet.

Samples showed low grade copper, some gold and silver; Ni and Co were not there. This property is still considered interesting from a copper standpoint. Bornite was in evidence in several places. Mineralization was in a basic rock. Stain was very extensive. Detailed mapping might do some good.
