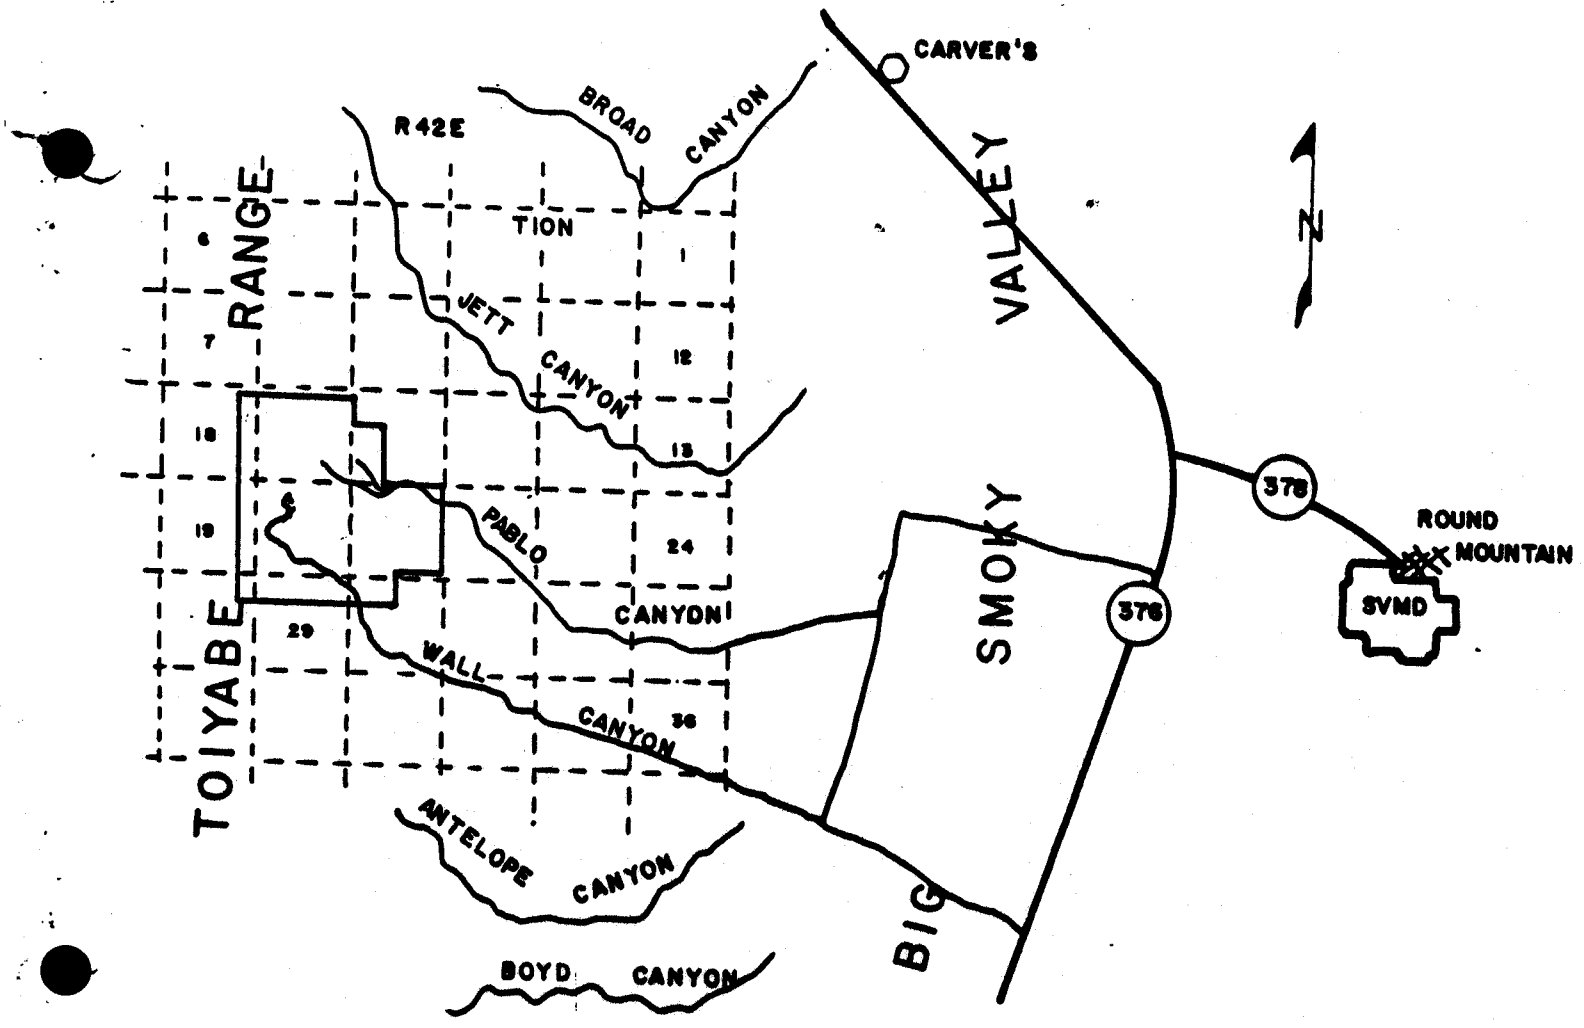

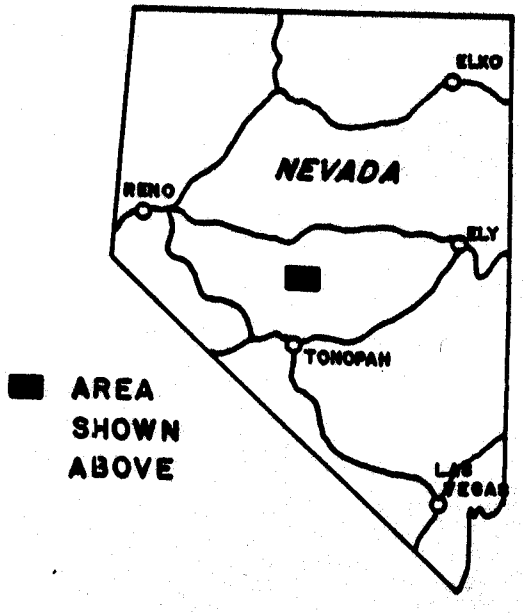

FIG. 1. WALL CANYON PROJECT LOCATION

SECTION I

1.1 Purpose of Report

The Nevada Bureau of Mines has written three reports, with sections dealing with the geology and mineralization of the Big Horn Mine area. The recent work by the Nevada Bureau of Mines, which was in conjunction with the U.S.G.S., and the work by the mine owners has established a better and more complete identification of the geologic formations of the area. In turn, this has lead to a better understanding, regarding ore controls.

This report is directed with the intention of presenting a geologic overview of the area and of presenting a more complete picture regarding the geologic controls of the mineralization at the mines. Finally, this report might be used by persons unfamiliar with the area, as a reference.

To accomplish this, a review of the regional geology, taken, in part, from the recent Nevada Bureau of Mines Report, as well as data from the older reports. From this, local concepts can be understood and in the area where information was previously lacking, geology, as it effects mineralization, can be identified.

The mine area consists of the consolidation of four separate mine groups. In this report, (1)the properties known as the Big Blue, Mammoth, Big Bananza, Bullwacker, and Blue Jacket will be referred to as the West Workings. (2)The Copper Rivet, Copper King, and the Temple-Belmont Group will be referred to as the Central Workings. (3)The South Workings includes the Mary Bennet, B & Me, Comet, Red Bluff, Anaconda, and the 1891. (4)The East Workings consist of the Last Chance, Whitby, Ashby, and the Calidonia. The South Workings include the first known workings in the Wall Canyon-Pablo Canyons area, although some of the earliest locations refer to other existing claims, of which there is no written record.

1.2 Geography

The general area where the Big Horn Mine Group is situated, is considered to be semi-arid, although this location is much wetter than most of the mining districts in Nevada. Annual precipitation is about 14 inches; and higher than average snowfalls occur on the property. Sometimes three to four feet of snow accumalate. Access to the mine is usually from April until late December, although during mining operations, the roads are kept open year-around will minimal effort.

The Big Horn Mine Group is located on the East slope of the Toiyabe Mountain Range and is in the Toiyabe National Forest, Nye County, Nevada and stand at an elevation ranging from 7700 to 8200 feet. Vegatation consist of native grass, sage, buck brush, mountain mohogany, juniper, and pinion pine trees.

There are several springs on the property. Summer daytime temperatures rarely exceed the low 90's F. and night-time temperatures are cool. Winter temperatures are cold with freezing temperatures common.

SECTION II

2.1 Physiographic Provines

The Big Horn Mine Group is located in the Great Basin, which covers most of Nevada. The Great Basin is characterized by numerous block faults, North-South trending mountain ranges and valleys. This block faulting started 17 to 20 million years ago, in the Late Tertiary times, thus creating many mountain ranges in Nevada with tilted volcanic rocks "perched" on top of the range. The Toiyabe Mountains being one such range.

2.2 Regional Geology

Mr. Kleinample, U.S.G.S. and Mr Ziony recently published, through the Nevada Bureau of Mines, a geologic report on the northern part of Nye County, Nevada. The regional geology, pertaining to the Toiyabe Range is thus reported.

"Northern Nye County, that part of Nye County north of the 38°, and occupies some 11,000 square miles of Central Nevada. Topgraphy of the region, is characterized by a series of alternating nearly north-south trending ranges and intermontone valleys commonly on the order of several thousand feet and in some places, nearly 7000 feet deep.

Bedrock, exposed mainly in the mountain ranges and pediments, includes sedimentary,igneous, and metamorphic types and ranges in geologic age from PreCambrian to Quaterary (Pleistocene). Pre-Cenozoic rocks extend across the region, with chiefly sedimentary strata, that spans the Paleozoic Era, lying in the east and central parts. In the far western part, sedimentary stratas are commonly interbedded with metavolcanic rocks and are exclusively late Paleozoic (?) and Mesozoic in age. In general, most of the Paleozoic strata change in facies from east to west. In northern Nye County; the eastern rocks consist in the main of a carbonate assamblage (platform facies) that yields in the central and western regions to a mixed carbonate-shale transitional assemblage (possibly either back-arc or slope origin). A volcanic detrital assemblage with near-shore elements dominates the Late Paleozoic (?) and Mesozoic sections in the extreme western part of northern Nye County and is possibly of island-arc or back-arc basin orgin.

Plutonic rocks outcrop in widely scattered bodies of small area extent in the western half and in the far eastern part of northern Nye County. Most of the

plutons are pre-Cenozoic and Cretaceous; however, at least one, in the Toquima Range, is Jurassic. Several hyabassal granitic masses exposed in the White Pine Range (eastern Nye County) and one in the Toiyabe Range have been dated radiometrically as Mid-Tertiary. A few other granitic plutons in eastern Nye (Grant and Quinn Canyon Ranges) were similarly dated as Tertiary, but at least the Grant Range body at Troy may be a radiometrically reset Cretaceous pluton.

Cenozoic rocks in northern Nye County consist chiefly of arealy very extensive, volumious, and thick pyroclastic material in ash-flow sheets of silicic to intermediate composition. The sheets are locally as thick as about 20,000 feet, and the older ones, Early to Middle Oligocene, are confined to the central and eastern parts of the region. A lesser volume of extensive and locally thick andersite to dacitic lavas and associated intrusive and protrusive masses are intercalated with the tuff sheets near the base of the volcanic section, particularly in the western and northern parts of the area. Similar intermediate and basic lavas also form a thin cap to the volcanic section in large parts of the western region. Rhyolitic lavas and clusters of protrusive bodies are much less abundant than the above-described rocks, but are found over a widely scattered areally and stratigraphically. Rhyolites locally lie at the base of the Tertiary volcanic section in the eastern and central parts of the County and in the central part, are as much as some 37 m.y. old.

Laterally discontinous Cenozoic sedimentary units scattered throughout the region form minor intercalations within the volcanic rocks and define periods of deltaic and lacustrine continental sedimentation into relatively ephemeral areally restricted basins. Such periods were most numerous in the Early and Middle Cenozoic.

A thin to thick deposit of Holocene sediments covers much of the intermontane valleys and generally directly overlies a valley fill that consists of at least several thousand feet of Late Tertiary and Pleistocene sedimentary rocks.

Geologists have traditionally considered that during most of the Paleozic, all of Central Nevada (including northern Nye County), lay within the broad north-trending Cordilleran geosyncline. The geosyncline may more properly be classed as a geocline bordering an early continental margin that extended northward across the region. Rocks of the carbonate asemblage on the continental platform (east of Long 117° W.) graded successively westward and downslope through an abrupt transitional assemplage into a coeval siliceous and volcanic assemblage that formed in an oceanic island-arc system.

A succession of Late Paleozoic, Mesozoic, and Cenozoic tectonic events have effected these rocks. The two earliest recognized events, the late Paleozoic

Antler and the suceeding early Mesozoic Sonoma orogenies, are marked by deformations that reflect large-scale mainly eastward-directed movement of an oceanic plate. Both events characteristically lead to the juxtaposition of the diverse facies described above--a telescoping effect--as demonstrated by rocks of the siliceous and volcanic assemblages resting upon strata of the transitional or the carbonate assemblage in the region of the Monitor, Toquima, Toiyabe, and Shoshone Ranges.

A relatively continuous period of Late Triassic and Early Jurassic sedimentation in the western part of the region was interrupted in the late Early Jurrassic by the Nevadan orogeny, an event that yielded its own characteristic orogenic assemblages of course clastic rocks (Dunlap Formation) deposited within restricted basins of the orogeny. Folding and trusting associated with this event were directed southward, then eastward, and finally, terminated with high-angle faulting and widespread plutonism ending the diastrophism.

The eastern part of northern Nye County was affected by major deformation during Laramide time (Sevier Orogeny) in the Late Mesozoic. Eastward-directed overturned folds and trusts with chiefly younger strata thrust over the older characterize this event and are well displayed in the Pancake, Quinn Canyon, and Egan Ranges.

Cenozoic tectonism is distinguished by widespread volcanism throughout the county, which mainly preceded basin-and-range normal faulting. Cycles of volcanism and erosion, epecially in the Oligocene and Miocene, led to the formation destruction, and local preservation of calderas, shields domes, and other constructional volcanic features. Caldera (caldron) complexes are of major significance in the volcanic evolution of the region: enormous volumes of ash-flow tuffs spread out for scores of miles from localized eruptive centers and then collapsed over the vents along subcircular and elliptical faults to form subsided caldrons. Calderas of different ages commonly impinge and coalesce to form diversely aged complexes, and the later calderas may partly obiterate or conceal earlier ones.

Transcurrent faults are postulated by some geologist to have been active in the Tertiary and indirectly may account for part of the disruptive segmentation seen in the present outlines of some mountain ranges and valleys. One system of arcute northwesterly trending transcurrent faults may have sheared apart a postulated major late Oligocene caldron in the north Reveille Range. The shearing of the caldera appears to have ended about 19 m.y. ago with the injection of dikes along some of the faults.

The basin-and-range normal faults, which generally strike north to northeast, represent the last stage of structural evolution of the region and account for

the present basin-and-range topography. Major movement along most of the faults apparently postdates the Oligocene and Early Miocene welded tuffs, and there has been recurrent movement to the present time along many of the faults. The Tertiary domical and block uplifting of the White Pine and Grant Ranges is postulated to have generated gravity slides and low-angle faults that account for numerous displaced bedrock blocks in the area. Other landslide masses and megabreccia units comprising Paleozoic and Tertiary rocks exist elsewhere within the Tertiary volcanic section and probably formed either by gemorphic modification of caldron or shearing and brecciation along major faults.

The principal metallic and nonmetallic commodities produced in northern Nye County have been gold, silver, antimony, lead, tungsten, mercury, petroleum, and magnesite and related minerals. There has also been production of zinc, copper, arsenic, gemstones (chiefly turquoise), brines, talcose minerals, sand, gravel, clay, and dimension stone (including travertine). Occurances of some commodities for which there is no reported production include: uranium, vanadium, selenium, manganese, nickel, glass (perlite and pumice), silica, and zeolites. Other commodities for which there generally has been some small production include chiefly barite, fluorspar, and molybdeum.

Hoist rocks for the ore deposits in the region are diverse in age and type and include Lower to Upper Paleozoic and Mesozoic (Triassic and Jurassic) sedimentary and volcanogenic strata, Jurassic, Cretaceous, and Tertiary plutonic rocks, and Tertiary volcanic and Cretaceous (?) and Tertiary sedimentary rocks. The major part of the silver and much of the mercury production has come from Tertiary rocks --Tonopah and Tybo for silver and Peavine and Union for mercury. Most of the lead in northern Nye County has come from Tybo from the same hoist rock as the silver.

The bulk of the gold came from mainly deposits formed during Tertiary volcanism, although many of the gold deposits are genetically or spatially related to Mesozoic intrusive rocks. Placer gold deposits of Tertiary age yielded much gold at Manhatten and Round Mountain. Fluorspar is also everywhere associated with Tertiary volcanism, however, large deposits may be found in Paleozoic carbonate rocks. Magnesite at Gabbs is in a Tertiary dolomite host rock, but could have been formed in the Late Cretaceous or Early Tertiary.

Undiscovered metallic and nonmetallic ore bodies probably remain in the mountainous areas of the county, but deposits hidden beneath alluvium in the extensive intermontane valleys are also increasingly being sought. It is expected that some of the deposits beneath the valleys may lie at mineable depths. These alluviated areas represent a larger unknown than mountainous terrian. Application of large-scale

exploratory programs using sophisticated geophysical, geological, and geochemical methods afford the most promise for sucessful exploration.

2.3 Geology of the Toiyabe Mountain Range, Northern Nye County

The southern two-thirds of the Toiyabe Mountain Range, one of th highest and most prominent ranges in the basin and range province, lies within Nye County, Nevada. The range is more than 100 miles long and between 7 and 10 miles wide, except south of North Twin River, where the range is more than 15 miles in width. At its' southern end, the Toiyabe Range merges with the Shoshone Range on the west. The highest point, Toiyabe Dome, has an altitude of 11,788 feet, and most of the crest, of the range, exceeds 10,000 feet. The range is elevated and tilted westward by frontal faults of large throw, which cut Quaternary sediments along the west side of Big Smokey Valley. A series of echelon normal faults of lessor throw, with the west (valley) side down, locally enhance the western bountry of the range. These are part of parallel high-angle faults, displayed as scarps in Quaterary sediments in the Reese River Valley, that probably outline a graben in the buried rock. This range and the Shoshone Range differ in topographic form from the Toquima Range by extending essentially unbroken linear mountain chains throughout their lengths. Major differences in geology from the north to the south in the ranges generally has not led to severe topographic segmentation; as in the Toquima Range.

Lower Paleozoic rocks (autochthonous Cambrian and Ordovician quartzite, slate, and limestone) unconformably suceeded by Permian sedimentary strata and inferred Late Paleozoic (?) sedimentary and metavolcanic strata and intruded by several large Cretaceous and Tertiary granite plutons and dikes, are exposed continuously along the east flank of the range as far south as Peavine Canyon. The relatively gentle western slope of the range and the crest of North Twin River is underlain by Tertiary ash-flow tuffs that dip gently towards the west but otherwise are little deformed. A 13 mile diameter, nearly circular, caldron underlies the highest part of the range between North Twin River on the north and Broad Creek on the south (Speed and McKee, 1976). Farther south, Tertiary silicic ash-flow tuffs and intrusive bodies and associated sedimentary strata and breccia form a structurally complex volcanic center. The inferred Peavine caldera is part of the center and underlies the southernmost part of the range.

The pre-Tertiary rocks between the Lander County line and San Juan and McLeod Creeks compose a northwest-dipping homocline, intruded by granite, and truncated on the east by a trust fault. Means (1962) has demonstrated that the rocks are complexly folded on a small scale and that two major phases of deformation occured,

The first deformation, tentatively assigned to the mid-Paleozoic Antler orogeny, produced a large north-trending cyncline overturned toward the east. The second deformation, ascribed to Mesozoic (possibly Sonoman) events, is evidenced by small scale folds whose axis trend northwesterly; it was accompanied by metamorphism and the pervasive development of cleavage. Discordant plutons were subsequently emplaced. A northeast-striking normal fault, downthrown on the west and with dip-slip of between 3,500 and 4,000 feet (Means, 1962, p.96), displaces pre-Tertiary rocks near the crest of the range.

Paleozoic strata between McLeod and Broad Creeks generally dip steeply to the west, and large scale isoclinal folds were noted by R.C. Speed (1974) in the Paleozoic section at Ophir Canyon. Farther south in the range, from Jett Canyon to Boyd Canyon, strata dip southwestward and are strongly folded on a small scale. Fold axis, which generally trend west-northwest, parallel to and coextensive with those in the Toquima Range to the east, probably record Mesozoic orogenic events. Several trust faults of relatively small displacement crop out south of Jett Canyon; some place older beds on the younger, whereas others place younger beds on the older. A relatively large fold exposed, at the mouth of Wall Cayon, is overturned toward the northeast and suggests tectonic transport in that direction.

High angle faults of probable Mesozoic or Tertiary age disrupt the Paleozoic strata and, in places, are intruded by granitic rocks, one mass of which was radiometrically dated at some 29 m.y. (Speed and McKee, 1976) at Broad Canyon. This mass forms a dikelike body and occupies a fault surface that separates Ordovician rocks from the Tertiary Darrough Felsite. Reverse faults, which are vertical or dip very steeply, are exposed north of North Twin River and in the valley of South Twin River. The northern segments locally emplace Late Paleozoic rocks or Early Paleozoic and may represent a folded part of the Golconda trust. Dip-slip Tertiary movement may have affected this thrust. The steepened thrust faults abut on east-striking fault in North Twin River Canyon on which, according to Ferguson and Cathcart (1954), strike-slip movement may have occured. This fault has been intruded locally by granitic dikes that are presumably correlated with the approximately 29 m.y. old body in Broad Canyon farther south. The Broad Canyon body intrudes a northeast-striking fault that crosses from Broad Canyon to Pablo Canyon and likewise could have undergone horizontal displacement. The fault separates relatively undeformed rocks on the north from intensely deformed rocks to the south. R.C. Speed (1975) considered the hypothetical strike-slip faults to coincide with and possibly represent caldron-bound faults of a caldera from which the Tertiary Darrough Felsite was

erupted. Strike-slip movement may thus not characterize these faults at all.

The inferred Peavine caldera, part of a complex Tertiary volcanic center impings on the southeastern part of the Toiyabe Range, where segments of the marginal caldron faults may be recognizable. One segment, conincident with Wood Canyon, separates complexly faulted and intruded tuffaceous rocks of the vent complex on the west from Early to Middle Tertiary rocks, including chiefly the Darrough Felsite on the east. An east-striking segmentm just west of the head of Boyd Canyon, separates mostly Permian rocks on the north from the inferred caldron. The structural blocks of Permian rocks may represent either the northern caldron wall or a resuged block near the wall. Another possible segment of the caldron wall and marginal fault may be exposed about 8 miles southeast of the mouth of Peavine Canyon, just south of Mud Spring (Bank Spring). There, the Tertiary volcanic complex abuts Paleozoic and Mesozoic strata along a contact that might represent the caldron margin but that coincides with the east-striking Pancake Range Lineament (Ekren and others, 1976). This Tertiary volcanic complex in the southernmost part of the Toiyabe Range is lapped on the west by the early Miocene Toiyabe Quartz Latite aand a subjacent andersite flow. The lapping rocks are relatively undeformed except for a gentle warp into broad north-plunging cyncline whose axis is approximately coincident with Indian Valley, and along which lies a small Quaternary Basaltic volcano at Black Mountain.

Northeast-dipping Permian (?) volcanic and clastic rocks are unconformable succeeded by west-dipping Dunlap Formation at the southern tip of the range. Limestone assigned to the Luning Formation locally has been thrust onto the Dunlap (Ferguson and Cathcart, 1954).

Nickel, platinum, chrome, and colbalt have not been produced in northern Nye County; however, interesting occurances are found in six general locations, including Jett, Antelope, and Twin Rivers Districts. The nickel and related minerals, chromium and colbalt, are nearly everwhere asociated with serpentinized ultramafites. The best deposits are believed to have been formed during alteration of some of these rocks, which had high primary contents of these metals. Depth of formation is not known. The geologic setting of the nickeliferous deposit at Willow Springs is similar to that at Candelaria, Nevada, where lower Paleozoic siliceous strata are unconformably overlain by Permian quartzite and grit of the Diablo Formation and the Lower Triassic Candelaria Formation.

The nickekiferous deposits near Manhatten are at least in part post-Early Triassic, because the Lower Triassic Candelaria Formation is mineralized.

Serpentinic (ultramafic) that is the source of the nickel and related metals possibly cut, alter, and mineralized the Candelaria. However clastic fragments of serpentine have been reported in the Candelaria (Poole and Wardlaw, 1978), and it is possible that the serpentinized rocks are faulted against older than the candelaria and the nickeliferous deposits in the Candelaria are secondary. Similarly, anomalously large amounts of nickel and other related metals at the other locations in the region may have formed by enrichment upon alteration of the serpentinite. The age of the metals' source rock, serpentinite, is not clearly established. Poole and Desborough (1973) believe that most of the serpentinites in the region were most likely derived from the Paleozoic upper mantle and were emplaced in their present position during the Antler orogeny. They considered that some serpentinite could have been remoblized from the Antler terrane or derived from the mantle during the Early Mesozoic Sonoma orogeny.

Between Pablo and Wall Canyons, roughly one mile northeast from the Big Horn Mine, is a dike of serpentinic rock. Specimans have been identified as being altered Gabbro and Periodotite (Poole, 1983), this dike is approximately one mile in length and from one to two hundred feet in width, although locally it may swell to three hundred feet in width.

Dolomitic masses faulted against the serpentinite may be Cambrian and are probably altered sedimentary beds and not carbonized serpentinite. F.G.Poole (1970), has raised the possibility that igneous rocks (for the serpentine), may be alpine-type dunites (Poole and Desborough, 1973). The structure implications of this matter would be major structures of pre-Tertiary age.

The Serpentinite bodies of the Toiyabe Range recently studied by F.G. Poole (1976) are believed to be along faults (also see Poole and Desborough, 1973).

Platinum was also reported in gold placer prospects that extend for several miles west from the mouth of Manhatten Gulch, Toquima Range. The prospects are in buried gravels in an area termed the "Manhatten Delta" (Tonopah Times-Bonanza and Goldfield News (1974a-1974b)). The platinum in the fanglomerates of the "delta" undoubtedly comes from serpentinized peridotite that crops out in the Toquima and Toiyabe Ranges and that must have been eroded away.

2.4 Antelope and Jett Mining Districts: Geology, Location, and History

The Jett Mining District originally conceived and encompassed only the drainage of Jett and Broad Canyons of the eastern flank of the Toiyabe Range. The name "Jett Mining District" was used in the much broader sense by Karl (1951, p.82) to include the Antelope District which covers the drainage of Wall and Antelope

and Pablo Canyons (organized in 1881), the Toyabe Mining District (organized in 1878) which included the basins of Boyd and Wood Canyons, and the Peavine Mining District (organized in 1906),but only included Horse Canyon and Peavine Canyon up to and including Toms' Canyon. The Peavine Mining District, as layed out by the miners, included all of the Peavine drainage, the Headwaters of the Reese River and the area west of these canyons to the boundries of the Superior Mining District. The Jett Mining district was organized in 1886.

The detailed description of these districts is taken largely from the published works of Ferguson and Muller (1949, p. 52-53 and plates 1 and 15), Ferguson and Cathcart (1954), Kral (1951) p.82-86, R.C. Speed and J.R. MacMillan (1972), and several other geologist who have described some of the mines in detail.

The earliest geologic map and geologic description are those by Emmons (U.S.G.S., 1870, p.320-348 and pl.13), who followed by some years the passage of John C. Fremont, who camped in 1845 at the hot springs (today known as Darrough Hot Springs). The springs were the site of human habitation long before the coming of the white man.

Production of these early years is almost all unrecorded and was probably relatively small; Lincoln (1923, p.172) mentions that considerable ore was shipped to Eureka and smelted (kral, 1951, p.83). Other sources mention the Toyabe District shipping ore to the mills at Jefferson. Until 1978, there were two ore wagons at the mouth of Boyd Canyon. Limited mining was done about 1921-22 on base metal silver deposits in Jett Canyon, near its' mouth, where another camp was started in the 1920's (Ferguson and Cathcart, 1954). The Gibralter Silver Mines Company of New York was active at this time on seven claims in Broad Canyon (Weed, 1922, p.1206). Base-metal silver and other precious-metal production has been less important since then.//

Greater values of ore have been mined since 1914 from deposits of antimony and mercury minerals.

Antimony production was started during World War I. The production during the 1935-1937 period only recently came to notice and the 1946-1953 production by the Last Chance Mining Company from the Big Horn Mine Group (Last Chance Mine). The Big Horn Mine Group, located on both sides of the divide between Pablo and Wall Canyons, has gone under other names in the past; Last Chance, Silver Divide, Bostian, Wall Canyon, Herd (?), and Francisco. (lawrence, 1963, p.140), who attributes to the mine about 738 tons of antimony ore containing 192 tons of antimony metal. The ore ranges in grade from 11 to 60 percent antimony metal. These production figures differ from D.E. White (unpublished data). Combined with other information, including the Eng. and Mining Journal, 1948a, p.114-115, suggest that actual production

from the Big Horn Mine was considerably higher, totaling about ~~5701~~ 5976 tons of ore containing ~~1690.68~~ 1860.28 tons of antimony metal.

The geologic setting of these districts is similar to that of the Twin River District to the north. With the expections noted below, the same pre-Tertiary rocks are present in both districts, differing chiefly in extent of exposure. Strata of the Cambrian Gold Formation and plutonic crop out over less area in these mining districts than in the Twin River District. As much as 200 feet (unmeasured) of shale, slate, and limestone of Silurian age, correlated with Kay and Crawford's (1964) Gatecliff Formation and Masket Shale, crops out in a thrust plate between Wall and Pablo Canyons; they next crop out in the Kingston District, Lander County. Also, several facies of Late Paleozoic strata are restricted to these districts in scattered locations south of Pablo Canyon; they are described in detail by Speed (1977a; 1977d). One facies is best developed near the head of Horse Canyon, where a dark-brown slope-formed unit 1,000-2,000 feet thick is composed of siliceous to calcareous shale and minor thin beds of intercalated dark-grey limestone. The facies is also exposed probably present in Boyd Canyon. A second more widely exposed facies crops out in the heads of Antelope, Horse, and Pablo Canyons. This facies consists chiefly of a moderate-yellow-brown to reddish-brown, shaly to slabby, locally fossiliferous and calcareous siltstone. Even though as much as 150 feet of the unit is exposed, the unit has not been precisely dated because the bevalve fossils are nondiagnostic. The third facies, a brown, medium to very course, gritty quartzitic sandstone attains its maxium development on the east slope of Horse Canyon near its head, where the strata are about a few hundred feet thick.

A small granitic body crops out just south of Boyd Canyon; another, farther south, is equally small. Compared to the other plutons, the latter exhibits an unusual feature in its contact relations with the surrounding Tertiary Darrough Felsite. Large zoned feldspar metacrysts to several centimeters long are developed within the contact zone, where numerous aplitic and less abundant granitoid dikes and sills cut the country rocks, and the metacrysts are especially conspicuous in the country rocks. Hyabyssal acidic porphyritic bodies, mapped as granite porphyry and quartz monzonite by Ferguson and Cathcart (1954), are scattered in the district. One, in the form of a very large dike that crosses Jett Canyon, includes mineralized quartz veins that were propected near the east end of the body in the early 1920s'. This dike is elongated northeastward because it intrudes a northeast-striking fault (Ferguson and Muller, 1949, pls. 1 and 15). Another even larger dike at Broad Canyon is about 30 m.y. old. Another such dike starts at the head of Wall and Pablo Canyons, and extends to the southeast for over two miles.

Serpentinite bodies as much as about 30 to 40 acres in extent are sparially associated with Late Paleozoic clastic rocks and the Permian (?) Pablo Formation. Some of the bodies were too small to show on the county geologic map, but most lie between Pablo Canyon, south to Horse Canyon, and several are within or near the Big Horn Antimony Mine at the head of Wall canyon. Some of the serpentinites are carbonatized, and some contain chrome (?); they are described as ultra-mafic rocks.

The oldest Teriary rocks are included with what Ferguson and Cathcart (1954) mapped as the Permian (?) Darrough Felsite. These rocks compose the bulk of that formation as originally defined, although Kleinample described the Darrough as restricted to a pile of dark-weathered rhyrolitic ash-flow tuffs. The unit, about 10,000 feet thick, is predominantly a series of welded tuffs, 22-27 m.y. old and is primarily divided on the county geologic map into middle volcanic sequence and the capping Toiyabe Quartz Latite, an ash-flow tuff sequence. The Tertiary volcanic statigraphy is grossly similar to that in the adjacent Cloverdale and Twin River Districts, but the middle volcanic sequence is less completely developed and less diverse lithologically in the Twin River District. In addition to predominant rhyolitic ash-flow tuffs, the middle sequence in the Jett and Cloverdale Districts is composed of air-fall and water-laid tuffs, tuff breccias, tuffaceous sedimentary rocks, and lava of rhyolitic composition. Brown-weathering andersite or dacitic lavas are volumetrically unimportant but form good marker horizons and are described as western region Cenozoic rocks. Rocks mapped as Esmeralda Formation by Ferguson and Cathcart (1954) in these mining districts, as well as the surrounding districts are, for the most part, clearly much older than the Esmeralda and Siebert Formations mapped in the regions south and southwest of the Toiyabe Range and have been included with the middle volcanic sequence. Updated, mildly tilted tuffaceous lacustrine beds just east of the mouth of Peavine Canyon are probably the youngest rocks exposed in the district and may correlate with the Siebert and Esmeralda Formations.

The structure of the district is basically like that described in the Twin River District. Three major phases of deformation have been recognized, and related to: (1) the late middle Paleozoic Antler (?) event; (2) the Early Triassic (?) sonoma (?) event; and (3) the Jurassic Nevada event. The Sonoma (?) orogeny has strongly affected only the allochthonous Permian (?) Pablo Formation, which is restricted to the Golconda (?) thrust plate (Speed, 1971). A series of thin imbricate thrust plates mapped between Wall and Pablo Canyons may be related to the Antler orogeny; other thrust faults in Jett Canyon probably have affinities to the Sonoma

orogeny and possibly to the Nevadan. Complex structural relations in the vicinity of Boyd and Antelope canyons have not been competely resolved, but Speed (1977a; 1977d) has described in detail the rocks and inferred tectonic events which may have left its imprint there and elsewhere in the range. Intense deformation was concluded prior to implacement of the ash-flow tuffs of the Darrough Felsite, because the Darrough is only slightly warped and tilted and overlies or locally intrudes the older deformed allachthonous Pablo Formation.

Basin-and-range normal faults are well developed along the range front, and locally the front exhibits faceted spurs. the faults locally define a series of blocks downstepped towards the valley; elsewhere a single major range-bounding normal fault was mapped. The youngest downdropped Tertiary rocks exposed are the middle volcanic sequence of western ranges. Other major Tertiary faults may be related to inferred caldron subsidence. Faults inferred to bound the postulated collapsed Peavine caldron, in the southern part of the mining district include; (1) on the east, the north-striking hoist-bounding fault west of Seyler Peak in Wood Canyon; and, possibly, (2) on the north, the 3½-mile-long-west-trending fault west of Boyd Canyon. The caldron is not well defined, but must extend west of Peavine Canyon beyond the district; its western limit may coincide with some of the faults near Cloverdale Canyon. Rocks within the postulated collapsed zone are mainly a complex of welded and nonwelded ash-flow tuffs, tuff breccias, and intrusive porphyries of siliceous composition. Some water-laid sedimentary strata composed of locally derived volcanic detritus are intercalated with the tuffaceous volcanic rocks. The capping Toiyabe Quartz Latite may conceal part of the caldron.

Speed and McKee (1976) have described another collapsed caldron in the northern part of the Jett District, between about Broad and North Twin River Canyons, from which the Tertiary Darrough Felsite was erupted. The major steep east and northeast striking faults coincident with those canyons and postulated to have incurred lateral movement by Ferguson and Cathcart (1954) are inferred caldron margin faults. (Kleinample, 1983, U.S.G.S., unpublished).

The mode of occurance of antimony is also similar throughout the range, but the deposit at the Big Horn Mine in the Antelope Mining District has been important commercially, and its description by Lawrence (1963, p.138-141) and other geologist are excepted.

2.5 Big Horn Mine Area Geology

The host geologic formation of the antimony veins is Silurian (Roberts Mountain Formation) composed mostly of thin bedded sandy lime from 600 to 1200 feet in width. This formation trends northwest and southeast, and is bound on all sides by thrust

faulting.

Geologic mapping of the claim blocks identifies the carbonate rocks as mostly thin bedded sandly lime, but also containing limestones, silty limestones, carbonate shales, sandstone lenses, and siltstones.

Based on the lithology and similarity to rocks identified as Robert Mountain Formation in the lower Wall and Pablo Canyons (Mullen, 1980), these rocks have been assigned as belonging to the Robert Mountain Formations. These rocks have been tilted 40° to 60° to the southwest. Overlying these rocks, along a thrust fault contact, identified as the Robert Mountain Thrust Fault, are cherts and shales of the Western Assemblage. The cherts and shales appear similar to rocks belonging to the Vinini Formation to the north.

Overlying the cherts and shales, also in the thrust fault contact are conglomerates and dolomitic limestones identified as belonging to the Antler sequence of the overlap assemblage. The upper thrust fault separating the Antler sequence rocks from the western assemblage rocks is identified as the Golconda Thrust Fault.

All three groups of sedimentary rocks are overlain by volcanics, principally welded tuffs derived from the development of the Toiyabe Caldera during the mid-Tertairy. The large number of felsic and mafic dikes within the sedimentary sequence are also believed to genetically relate to the development of the Toiyabe Caldera.

Mineralization within the claim block appears to be both fault and stratigraphy controlled. Surface mapping and subsequent drilling indicates that most of the antimony mineralization occurs in faults zones in conjunction with quartz veins and is either within or in close proximity to ultramafic structures, while most of the gold-arsenic mineralization occurs along favorable stratagraphic horizons in the carbonate units. There appears to be a slight age difference between the two types of mineralization with the antimony-quartz mineralization being slightly younger and cross-cutting the gold-arsenic mineralization. Plate 12 shows the cross-sectional relationship between the gold-arsenic and the antimony-quartz mineralization and the adjacent geology.

The two small hills, where the South Workings are located, are made up of Permian rocks, probably from a submarine lava flow (Poole, U.S.G.S., 1983) (Plate 2).

Ultramafic Occurances

Within the Robert Mountain Formations, and in the main confined to the limestone and thin bedded lime, are found lenses and pods, classified as containing ultramafic minerals, who's origin (Poole, 1983), along with the sometimes associated dolomitic rocks are the remants or rine of a prehistoric tectonic plate. The joints and planes of the limestone

shows the presents of the ultramafic minerals (identified by spectographic analysis as containing anomalous amounts of nickel, chrome, cobalt, and antimony). Some of the bright green mineralization has been identified as being "Mariposite", a bright green chrome mica. From the outcroppings, some 1/4 mile west of the West Workings, the limestone structure, which contains much of the ultramafic mineralization, can be traced, to the east, for a linear distance of some two miles or more.

Ultramafic mineralization is found on the dumps of the three main antimony mine areas, as well as many of the prospect pits and trenches, again suggesting a close relationship between the antimony mineralization and the limestone-ultramafic formations.

Intrusive Dikes and Sills

Just east of the West Workings, parallel to and in contact with the limestone, is a dike or sill of porphyry. This formation can be traced to the proximity of the Central Workings, where it is lost under the alluvial. This structure may trudicate against the N-S fault which transverses that area. At times this structure is not much more that a foot in width. South-east of the Central Workings, and striking towards the East Workings, outcrops a quartz-monzonite, sime 200 feet wide. North and northeast of the Central Workings, a dike of quartz-porphyry outcrops and strikes to the east. This dike crosses the north-south fault, east of the East Workings, and can be traced for more than a mile , to the east of the claim block. This granitic-porphyry dike lays on the north side and is parallel to the limestone-ultramafic formation and is separated from it by some 100 feet (more or less) of sandy lime and shale.

Faults and Fault Structures

As previously noted, the area abounds in faults and thrust faults. The geology map of the claim block notes the many faults. Some five hundred feet south of the East Workings is an outcroppings of solidified conglomerate, containing grains and uneven pieces (both in size and shape) of ultramafic mineralization. This outcropping may relate, indirectly, to the breccia zone located on the south side of the main vein, in the East Workings. This breccia zone is some 20-30 feet in width, and contains fragments of a dolomitic material, as well as small amounts of sulfides. As refered to earlier, the antimony-quartz mineralization is found in and along these faults in the form of veins, up to 12 feet in width, and elsewhere as lenses and pods, veins structures being the most common form. In all three workings, the veins are free from the wall rock on both the hanging and foot walls.

At the Central Workings, there are a series of antimony-quartz filled veins. None of the veins are normal to the host formations, as most of the veins cut across the strike and the dip of the formations. The host formation is almost always the thin bedded sandy lime, but in close association with the limestone-ultramafic formation. The quartz-antimony

veins are located on either side of, or in the case at the Central Workings, also crosscut through the formations. At the Central Workings, much of the antimony mineralization appears to lay in the fault zones under the limestone-ultramafic structure, although, above the 15 level, the mineralization at the surface is on the contact with this formation. Throughout the property, there are additional antimony-quartz veins which, to date, have not been developed, one such vein is located in the C-100 level.

The geochem program (1980) indicated the presents of additional mineralization between the Central Workings and the West Workings and also between the Central Workings and the East Workings.

At the West Workings, in addition to the Big Blue Veins (2), an antimony-quartz vein was discovered, in the hanging wall of the West Adit, prior to reopening this adit (1984). This veinlet is from 1 to 6 inches in width, and appears to be widening down dip. In places, the vein is solid stibnite and has the same general dip (SW) and strike (NW X SE) as the upper vein at the Central Workings (15 Level).

Mine Geology and Workings

The South Workings are not of the antimony-quartz vein system. This area is made of a Permain under-sea lava flow. The mineralization consist of chalcopyrite and a small amount of Molybdenum. Small pits, shafts, and a drift, some 125 feet in length, comprise these workings.

The East Workings, which includes the original "Last Chance Antimony Mine", is the easterly most known commercial antimony mineralization. North of the main vein outcroppings, was a small shaft on a second antimony-quartz vein. This area has since been worked over by a dozer which has destroyed the old workings. There are also several prospect pits in this area. This antimony-quartz vein is not well defined. The outcroppings of the East Workings can be traced for some 300 feet along the strike. There are three 40 feet deep shafts on this outcropping, as well as other surface pits. There is still antimony ore in these workings, with a mineralized width of from one to two feet. From the 230 foot crosscut, driven to intersect the vein, there was some 250 feet of drifting. A room is located between two of the stopes. The vein is accessable, but the drifts are caved. There was recorded 400 tons of 20 % ore mined from these workings during the First World War and an additional 100 tons of 30 % ore mined in 1946-47.

The host formation, on the south, is the thin bedded sandy lime, which is separated from the vein by some 20-30 feet of graphitic gouge, containing some sulfides and small pieces of dolomite (1 to 2 inches being normal), while on the north side the wall rock is the thin bedded sandy line in close proximity to the limestone-ultramafic and granitic-porphyry formations.

The Central Workings is the largest development of the Big Horn Antimony Mine Group containing over 3000 feet of workings. There were two shafts at these workings. The original shaft, now backfilled, was 115 feet deep (plus sump), and was developed by the C-15, C-60, C-80, and C-115 Levels. ("C" standing for "Central Workings"). The C-15 Level is now accessable from the surface. The C-60 and C-80 Levels are not accessable, nor are there maps of these levels. The C-115 Level is accessable from a raise starting on the C-140 Level and also from a winze off of the C-100 Level. The main shaft is a two compartment shaft, 185 feet deep (plus sump), and was developed by the C-100, C-140, and the C-185 Levels. All Levels are referenced from the collar of the original shaft.

In the main, the host formation is the thin bedded lime or shale, with the limestone-ultramafic in close proximity. There are a series of somewhat parallel veins and stringers, striking in two directions. The main North-South vein is within a thin bedded sandy limestone and shale, which is wholly incompetent. As the C-60 and C-80 Levels are not accessable, the length and width of the stopes on these levels is not known, although; whenever the C-100 Level was driven into these areas, either through crosscutting, or raising, stopes were encountered.

The C-15 Level was driven on a NW-SE vein, which is crosscut by a second vein striking about 20° further NW-SE than the first vein. This second vein was not developed on the C-15 Level, although, this second vein appears to be the wider of the two veins. The drift is on a fault zone, which shows a some antimony and is from 18" to 36" wide. The wider vein appears to be some five feet wide with leses and pods of antimony. On the C-100 Level, crosscutting and raising has encountered stopes on both of these veins. On the C-100 Level, the main N-S vein was also stoped, to the south. A second N-S vein some, 18" to 24" wide, was stoped in several places. This vein was also stoped, from the C-115 Level to the C-100 Level. Where this N-S vein intersects the NW-SE veins, the area was heavly stoped on both NW-SE veins. Some of the ore, left in place is 5 feet in width. This area was also under hand stoped down to and below the C-115 Level. The C-115 Level is only accessable along the main N-S vein, and was stoped, from the winze area (off of the C-100 Level), to the south as far as the workings are accessable. Mr. Strom, operator from 1955-1958, suggest this drift and stoping was very extensive. The Vein on the north side of the C-145 raise, is some 2 feet in width, and carries some 12 inches of antimony in quartz, on the hanging wall and some 15 inches of sheet antimony and wall rock on the footwall. Down the raise, driven from the C-140 Level, this vein is from three feet wide, near the C-115 Level to some 12 feet wide

as it nears the C-140 level. The mineralization is in layers; of wall rock and sheet antimony, antimony in quartz, and solid antimony. Based on the statements of Mr. Strom; "this vein was not developed, to either the north or to the south, to the full extent of the ore zone." The C-140 also drifted on one of the NW-SE veins. The mine was shut down at this time due to the bottom dropping out of the price of antimony (see settlement sheets).

The C-185 Level was in the process of being developed, at the time the mine was shut down. The NW-SE vein was drifted on for 50 feet with ore bunkers placed at these points. As the main N-S vein was not crosscut, the grade and width of this vein, on the C-185 level is not known.

There is another vein, on the C-100 Level, other than being crosscut, it has not been developed. Good ore, on the C-100 Level, can be seen. Most of the antimony production, since 1947 has been from the Central Workings.

The West Workings consist of a shaft, at one time some 100 feet deep, on a NW-SE vein which carries some 6 ounces of silver. A second parallel vein, to the north, carries about 4 ounces of silver. A three hundred foot crosscut was driven under this general area. The part of the crosscut which was driven under the shaft area is caved. A dozer cut, small incline shaft, another adit not yet opened, and many prospect pits dot the area. Much of the prospecting is around a sizable outcropping of limestone-ultramafic mineralization. This area was known, in the past, as the "Big Blue Area".

2.6 Recent Geological Work on the Big Horn Claim Group

Regional geological reconnaissance performed during 1980 discovered the existance of a substantial area of arsenic, antimony, and gold mineralization in the Paleozoic sediments around the Big Horn Claim Block. Surface geochemistry, geology, and drilling performed during 1980-1982 partially outlined the original area of mineralization and located additional areas of potential favorable mineralization.

Surface geochemistry including both rock chip samples from outcropping structures and also soil samples. A total of 269 samples were collected and assayed for gold and silver. Many of the samples were also checked for copper, lead, zinc, arsenic, antimony, and molybdenum. The results are in the index. Plate 1 shows the sample locations. From these sample locations, the results were recorded and geochem maps for the various minerals were made.

A surface geological map was constructed over the central portion of the claim group and is included as Plate 2.

Forty-four rotary drill holes were drilled to depths of 195 to 500 feet. Samples

were collected every five feet and assayed for gold and silver; with some being assayed for arsenic and antimony. A few were assayed for copper. These drill hole results are included in the drill hole logs and their locations are shown on plate 14. The one core drill location is also shown on plate 14 and a sketch of the core is in the core log.

Geochemistry

Surface geochemistry outlined several areas of substantial gold-arsenic and antimony-quartz mineralization. The largest zone of mineralization extends over a strike length of 4000 feet with an average width of 500 feet. An additional anomaly covering a minimium area of 1000 feet by 1000 feet occurs on the western edge of the Big Horn Claim Group. Geochemistry contour maps for Au, Ag, Cu, Pb, As, Sb, and Mo are shown on plates 4 - 11.

In general, Au As, and Sb anomalies occur in rocks identified as belonging to the Robert Mountain Formation of the eastern carbonate assemblage.

Drilling

This drilling program resulted in proven ore reserves of 309,000 tons averaging 0.027 oz/ton Au, probable ore reserves of 411,000 tons averaging 0.025 oz/ton Au, and inferred reserves of 500,000 tons averaging 0.025 oz/ton Au for a total of 1,220,000 tons averaging 0.025 oz/ton Au. The gold mineralization occurs in two zones, the largest of which averages 300 feet in width and can be traced for 1,900 feet along strike. Only one area, 400 x 300 feet of this mineralized zone has been drilled in detail. Gold mineralization occurs with an average thickness of 100 feet.

Gold and arsenic isopach values for the mineralized horizon in Zones I and II are shown in Figures 2 and 3. Gold values were averaged over the best fifty foot interval in the drill holes; while arsenic values were averaged for the entire drill hole. Cross sections showing correlations between mineralization in the drill holes in Zone I are shown in Figure 4.

The potential gold resource on this property is from 5,000,000 - 10,000,000 tons of ore.

The gold mineralization is open in both zones along strike to the northwest and down dip.

Conclusions

Gold

There are significant areas of gold mineralization within the carbonate rocks exposed on the Big Horn and WC Claim Groups.

Gold mineralization appears to be mostly associated with arsenic and probably occurs as minute particals of free gold contained within the arsenopyrite grains.

Gold mineralization encountered in the drill holes correlates well with up-dip surface arsenic anomalies.

Antimony

Although antimony was not the target of this exploration program, anomalous amounts of antimony was encountered both in the surface samples and in the drill holes during the 1981 phase of the program. Both surface samples and drill hole assays showed anomalous amounts of antimony between the West Workings and the Central Workings, and the Central Workings and the East Workings, as well as anomalous antimony values parallel to the existing workings.

Ultra-Mafic

Ultra-Mafic mineral, as shown by the anomalous amounts of Chrome, Nickel, Cobalt, and Antimony can be traced, by a series of lenses and pods over a width of 1000 feet and along the strike length for some 2 miles. Also note the results in drill holes No. 31, 32, 33, 34, and 35; where assays for Nickel and Cobalt were reported.

SECTION III

MINING HISTORY

3. General Notes

As shown in the several State of Nevada Bureau of Mines Reports, U.S.G.S. Reports, and other articals refering to the Last Chance Mine, there is general confusion regarding the identification of the different levels, at the Central Workings.

As Nevada Antimony, (as a partnership, and later a Corporation), held the property from 1934 until 1980, their maps should have the correct level identification. The following level idenfication of the Central Workings Levels is based on the 1954, and later 1958 Nevada Antimony Maps. The 1954 Mine Map of the Central Workings, as supplied by Nevada Antimony Corporation was checked against the Mine Map in the possession of Mr. George Strum, Leasee from 1955-1958. All mine levels are referenced to the collar of the "ORIGINAL" shaft, as shown on the 1934 Claim Map Plate, filed with the Nye County Recorders' Office, for Nevada Antimony.

The levels are as follows: 15, 60, 80, 100, 115, 140, and the 185. The reason for the confusion is probably the fact that the original shaft, the point of the original 1934 survey, has been backfilled, and no longer exist. From the original shaft, there were four development levels; the 15, 60, 80, and the 115. The shaft was 115 feet deep, plus sump. The present adit, just northwest of the old generator building, is the original 15 level of the old shaft. It was, originally, 15 feet down from the collar of that shaft.

The bottom level (115) of the original shaft, lays between the adit level (100) and the 140 level of the main shaft.

On the Nevada Antimony Maps, this level (115) is identified as a Sub-level, and was not reestablished until 1956, when a raise, from the 140 level broke into it. A winze was then sunk from the 100 level to establish faster access to the level. As the bottom level of the original shaft was the 115 level, we have reestablished that number to this level.

The original "Last Chance Antimony Mine" (Wall Canyon or Silver Divide Mine) is what is now known as the East Workings.

3.1 Published History

Two Nevada Bureau of Mines Reports; Bulletin 50; by Victor E. Karl; "Mineral Resources of Nye County, Nevada"; and Bulletin 61, by Edmond F. Lawrence; "Antimony Deposits of Nevada", both have sections reporting on the Last Chance Antimony Mine (refered to as the Central Workings in this report). These reports are hereby combined to eliminate overlapping material.

"The mine was originally located in 1915 (1881). Four hundred tons of ore containing an average of 20 percent antimony was reported shipped during World War I. Several sources indicate that 14 tons of ore containing an average of 60 percent antimony and 29 tons averaging 45 percent antimony were shipped in 1939; and that 7 tons of 34 percent antimony ore were shipped in 1940. The shipments made during 1939 and 1940 were made by F. A. Vollmar, who leased the property. (Hugh Cameron, nephew of Vollmar, who worked in the mine from 1939-1942, states "the ore produced by Vollmar and shipped to Vollmars' mill at Minden, Nevada was much higher that the figures stated by the State of Nevada, Bureau of mine reports"). In 1941 and 1942, Fred J. Delongchamps leased the property and 214 tons of 10 percent antimony ore and 30 tons of 30 percent antimony ore were shipped. (During 1946-1947, the Last Chance Antimony Company shipped 100 tons of 30 percent antimony ore).

In 1946, Mr. N. L. Brown (and eta, under the name "Last Chance Antimony Company" leased the Grouse Springs Group of Claims (original Last Chance Antimony Claim), and in 1949, they leased the balance of the claim block). A 255 foot adit was driven which connected the main shaft at the 100 level to the surface. A 50 ton floatation mill was erected, later the mill was changed to tables and jigs. Later, a small rotary furnace and bag house (condenser) were constructed (to produce antimony trioxide at the mine from mine run ore). The operations were suspended in 1953 (the shut down being caused, in part by the drop in antimony prices and also from the poor recovery of antimony experienced at the mill). (In excess of 3000 tons of antimony ore containing 30 percent contained antimony were mined from 1948 through 1953).

In 1955, the mine was under lease to the Great Western Mining Company (, Mr. George Strum, General Partner). The last reported production (1957-1958) was 29 tons averaging 15 percent antimony and 15 tons of ore averaging 11 percent antimony (See elsewhere in this report).

The mine (Central Workings) was developed by a 180 foot shaft, with a total of 300 (3000) feet of drifting on the (15), 60, 80, 96 (100), 126 (115), (140), and 175 (185) foot levels. (see elsewhere in this report). The adit connects to the 126 (100) foot level. Other workings elsewhere on the property includes a 180 foot adit (15 level) above the shaft, several open cuts and short adits".

3.2 Unpublished History

Early mining claims, in the Wall Canyon Area, were recorded as early as 1881. The Antilope Mining District was organized during that year and encompassed the drainage

basins of Pablo, Wall, and Antelope Canyons. Some of the earliest claims were referenced to existing claims, enferring there were claims already in existance when they were located. The records of these earlier claims may have been destroyed in the fire at the Belmont Court House.

The first claim, of which there is still records, was the Mary Bennet Mine, located on June 5, 1881, by Adam McLeon. This claim was soon followed, on June 24, 1881, by the following claims; B and Me, located by A. A. Bruce, Charles Curelley, and Adam McLeon; the Comet Mine, located by F. C. McNeil, A. A. Bruce, and Adam McLeon; and another Mary Bennet (an extension of the Comet Mine), located by A. A. Bruce and J. Bellyea.

The next claims of record were dated 1885. Other claims may have been recorded in the Antelope Mining District Recorders Book, which has since been lost. On June 24, 1885, Mr. M. Curtiss located the Whitby Claim on the divide between Wall Canyon and Pablo Canyon (this is the first claim of record in Pablo Canyon), and refered to as being 1/3 mile north of the Red Bluff Mine (no record of a Red Bluff Mine as of this date). Then on November 19, 1885, Mr. Curtiss recorded the relocation of the Red Bluff Mine.

There is no record of other mining claims being located from 1885 until April, 1891. Again, the loss of the district mining recorders book may account for this. On April 30, 1891, the Ashby Mine was located by D. H. Jackson. On the same date, F. C. McNeil located two claims, the Anaconda Mine and the 1891 Mine. All of these locations were in Wall Canyon. On May 2, 1891, the Northwest Extension of the Ashby Mine was located as the Sandusky Mine by Mrs. May Deady and Mrs. Johana Compton.

On June 16, 1891, F. C. McNeil amended his Anaconda Claim Notice and stated " that a stone monument marks the boundry between the Ashby and the Anaconda Claims". On June 16, 1891, D. M. Jackson also amended the Ashby Claim Notice. On August 5, 1891, both D. H. Jackson and F. C. McNeil locate the Last Chance Antimony and Silver Mine. On August 14, 1891, they also locate the Calidonia Mine. Through 1894, the records show Proof-of-Labors' were filed on the Anaconda, Ashby, Calidonia, and the Last Chance Lode Claims.

On January 1, 1896, William O'Brein relocated the Anaconda Mine as containing Antimony, Gold, and Silver. On the same date, Mr. John Thorp relocated the Red Bluff Claim and shows it contains antimony. He also relocated the Ashby Claim, which he

renamed the "Confidance", and states it contains antimony. Next, Mr. Thorp relocated the Caldonia Claim as the San Domingo Claim.

On November 25, 1896, the first claim was located in Pablo Canyon. This claim was called the "Big Blue" and was located by S. D. Ott, original owner of the Pablo Canyon Ranch (which lay at the mouth of Pablo Canyon) and Mr. J. F. Stebbins (of later Round Mountain fame).

On January 1, 1898, Mr George A. Thorp located the Mammoth 1 and Mannoth 2 as being 1500 feet NW and 1500 feet SE from the shaft. The ores contain Antimony, Gold, and Silver. This shaft is thought to be the shaft on the Big Horn No. 7 (Big Blue Shaft).

The Anaconda Lode was again relocated on September 24, 1898 by F. C. McNeil and Walter Gayhart. The Dewey Mine (a relocation of the Emma Mine (no record of the Emma Mine)) was located on January 24, 1899 by William McCann (of later McCann Canyon) and on February 14, 1899, he also located the Big Bonanza Claims. These claims are though to be some 1500 feet southwest from the Big Blue Claims, where prospects of an early age have been found. On June 13, 1899, Mr. McCann located the Copper King Claim. This claim is thought to be in the area of the present generator building.

On April 9, 1903, the Chloride Mine was located and on April 20, 1903, the Bullwacker Mine was located. These last two locations were by James Frasuer, Lane Oakley, and J. B. Morris. These claims are probably the relocations of the Dewey and Big Bonanza locations of Wm. McCanns'.

Between October, 1905 and November 29, 1905, Henry Rixon, John McAuliffe, William Lynch, and George Lynch located the Temple No. 1, 2, and 3; the Belmont No. 1 and 2; the Ante Up, the Woodstock, the Atwater, and the Fortuna Claims. As some of these claims refer to the Henry Millet Ranch (Pablo Canyon Ranch (Ott had died)), it is assumed these claims were in Pablo Canyon rather than Wall Canyon. The Atwater Claim being at or near Pablo Creek and the others extending in a somewhat easterly direction from there. The importance of this group is, they undertook and completed a new road to the properties. This road was completed in 1906.

During 1906, the area being opened up by the new road, saw 63 new locations and another 49 locations in 1907. In 1908, only 3 new locations were recorded and in 1909, ten locations were recorded.

On April 22, 1910, Mr. J. E. Lindstrom and Otto Johnson staked the Copper Queen, the Copper Queen No. 1, 2, 3, 4, and 5; the Copper Queen Extension No. 1, 2, 3, 4, and 5

These claims were all in Wall Canyon and are thought to cover the area of the Big Horn No. 10, 11, 12, 14, and 19, in addition to the ground south and east of these claims, which is now covered by the WC Claim Group. The Copper Queen No. 5 and 6 were added on April 1, 1911, as being on the divide between Wall and Pablo Canyons. The Copper Queen Group probably covered the same general area as the Temple-Belmont Group.

On July 17, 1910, the Big Blue Ledge was relocated by Mrs. H. P. Millett, Charles Wilson, and J. C. Salaman, as the Blue Jay No. 1 and 2.

From January 10, 1911 thru April 1, 1911, Otto Johnson and J. E. Lindstrom expanded their Claim Group to include the Copper Chief No. 1, 2, and 3; the White Cliff No. 1 and 2; the Eagle, and relocated the Last Chance No. 1 and 2.

On May 22, 1912, with John Wiekland, this same group located the Copper Mountain No. 1, 2, and 3. On September 4, 1915, John Wiekland, Otto Johnson, and Oscar located the Antelope Claim in Wall Canyon.

On January 1, 1916, C. G. Phillips located the Silver King (old Caldonia), the Anna Bell (old Ashby), and relocated the Last Chance Lode Claim.

The forgoing outlines the early claim history of the area, as far as mining records are concern. This history can be broken into four principal work areas. The earliest discoveries were in the South Workings Area and include: the Mary Bennet, B and Me, Comet, Red Bluff, Anaconda, 1891, and the Copper Queen Group. None of these properties have any known production.

The West Workings includes; the Big Blue, Blue Jays, Mammoth, Big Bonanza, and the Bullwacker. Although this area has no known production, it is possible that a small amount of ore was mined. The extent of the workings, and the West Adit being driven to intercep the Big Blue Shaft, would suggest good mineralization may have been encountered in the shaft.

The East Workings recorded the earliest recorded production; that from the Last Chance Mine by the Silver Divide Mining Company (C. G. Phillips). This area includes the Last Chance, the Whitby, the Ashby, and the Calidonia.

The Central Workings has produced most of the antimony ore since 1919. This area includes; the Copper Rivet, Temple-Belmont Group, and the Copper King.

3.3 Antimony Production; Published and Unpublished

The South Workings has no known production. There are stringers of Copper bearing mineralization (with a small amount of molybdenum). These stringers are in the Permain

Formations, (under sea lava flows), which differ from the host formations which contain the antimony mineralization. These workings contain some 125 feet of crosscutting, as well as many small pits, shafts, and opencuts.

The west Workings has no known production, but the size of the dumps suggest the possibility of favorable mineralization was encountered in the Big Blue Shaft. There is some 300+ feet of crosscutting in the West Adit of the West Workings, with a second heading (caved) towards the Big Blue Shaft. There is a second vein, northeast of the Big Blue Shaft Vein. This second vein carries Silver, Antimony, and Copper. A third vein, in the hanging wall of the portal of the West Adit, was discovered while facing up the portal of the West Adit. The East Adit of the West Workings has not yet been reopened. There are numerous open cuts, prospect pits, small shafts, and several dozer-cuts on the veins in this area, suggesting wide spread mineralization.

The East Workings produced the earliest reported antimony production. The main workings is the "**ORIGINAL**" Last Chance Antimony Mine. This workings and the leasee, the Last Chance Mining Company (1946-1953), has given the whole area the name of "Last Chance Antimony Mine". In addition to the 400 tons of ore produced from these workings during the First World War, an additional 100 tons of ore containing 30 percent contained antimony was produced from 1946-1948 by the Last Chance Mining Company. Originally, from 1946-1948, the Last Chance Mining Company only leased the Grouse Spring Group of claims. It was not until 1949 that the Last Chance Mining Company leased the balance of the claims, which comprised the Nevada Antimony Group of Claims.

The Central Workings include the Temple-Belmont Group, which had developed the ground with, what on the Nevada Antimony Claim Group Map is shown as, the "original shaft". This shaft is the "point of origin" for the 1934 Nevada Antimony Claim Map Survey. The depth of the shaft, at this time, is not known, but the 15 level and possible the 60 level did exist. Each of the three groups, which made up Nevada Antimony, located part of the ground. The names of each sub-group are; the Grouse Spring Group, the Last Chance Group, and the Silver Martin Group. All of the claims were surveyed as one group, with the shaft as the "point of origin" for all of the claims. The three claim groups were to be known as the Last Chance Antimony Mine Group. Much of the early ore produced by Nevada Antimony, came from this shaft, from the existing levels. Nevada Antimony deepened the shaft to the 115 level and sump. The 80 and 115 levels were established and most of the ore mined during 1935-1937 came from these four levels.

From 1939 until 1945, several leasors operated the property, but were unwilling to expend the money needed for further development. In 1939, F. A. Vollmar leased the

mine and mined on the existing levels. In 1941-1942, Antimony Products Company, Fred J. Delongchamps, mined some 244 tons of ore from the existing workings. The shaft was weakened from leasees robbing shaft pillars, and the mine was shut down. The Last Chance Mining Company only lease the Grouse Springs Group of Claims, due to the condition of the shaft. When Additional financing became available, in 1949, they leased the balance of the claims and undertook the sinking of a new shaft (now called the "Main Shaft"). The Last Chance Mining Company leased the combined groups of claims until 1954, when a drop in metal prices and the poor recovery of antimony caused the closure of the mine. During the tenure of the Last Chance Mining Company, they established a regular mining camp; a 32 man bunk-house, a cookhouse, warehouse, compressor-generator building, shop, water wells, water lines, air lines, and power lines. Due to the unstable ground around the original shaft, the shaft was backfilled. A new shaft was sunk 180 feet deep, including sump, and levels were established on the 100, 140, and 185 levels; using the collar of the original shaft as the reference for mine levels. A 225 foot crosscut was driven to the surface, from the 100 level to facilitate pumping mine water and ore access. A 50 ton/day mill and bag house was constructed. The mill, from the start, had problems. According to many who worked at the mine and mill, many of the problems were man made. The mine and mill were shut down in 1954 after some 3275 tons of ore were mined, containing 1091.6 tons of antimony metal.

In 1955, the Great Western Mining Company, Mr. George A. Strum, General Partner, leased the mine. They also contracted to have the ore milled at the Stevens Mill (the old Clifton Mill) in Austin, Nevada. In addition to the ore recovered on the 100 level, development was started on the 140 level. When the main N-S vein was crosscut, it was drifted on for some 60 feet. A raise was driven up the orebody until the 115 level was located. Stoping started where the ore was 12 feet wide. Almost immediately upon starting the stoping, the bottom fell out of the price of antimony (1957). The stopes were shut down. The mine was kept on a "standby state" until 1958, when the equipment was removed. During the time the mine was kept at the "standby state", the 185 level was established and a crosscut was driven to the NW-SE vein, the vein drifted on for 50 feet, and ore bunkers were set at the end of the two drifts. When this project was started by the Great Western Mining Company, it was assumed, that the price of antimony would soon recover. In 1958, after making quarterly payments for one year after the mine had stopped producing ore, the lease-option to purchase agreement was returned to Nevada Antimony. The last concentrates were sold to settle the accounts (see settlement sheets). The Great Western Mining Company stated "proven reserves on

the 140 and 185 levels as being some 3000 tons of ore averaging 30 percent contained antimony. Total estimated probable and possible ore reserves, for the whole mine, were stated to be 22,000 tons of ore containing some 29+"percent contained antimony".

In 1965, the mine was under lease to the Hercules Mining Company, of Austin, Nevada. Mr. F. A. Vollmar and Mr. William Noach being the two main figures. Some 550 tons of ore was stockpiled on the property. Several shipments were made, and when one of the financial backers found there had been ore shipped for which he had not recieved his percentage, he shut the mine down. The ore grade was 40 percent contained antimony. In 1973, without the concent of the mine owners, some 250 tons of hand sorted ore was shipped to Utah. After the fact, the mine owners became aware of what had happened. The ore graded 42 percent contained antimony.

The Central Workings consist of two shafts, The original shaft, some 115 feet deep, plus sump, and the maint shaft 180 feet deep. The original shaft has been backfilled. The present adit, just west of the compressor-generator building is the 15 level of the original shaft. Total drifting and crosscutting contains some 3000 feet of workings, in addition there has been stoping off of the 60, 80, 100, 115, and 140 levels.

Antimony production information, history, and ore reserves of the Big Horn Mine Area includes information provided by the following persons, during personal interviews or phone conversations.

1. Danny Daniels, Hawthorne, Nevada; Truck driver for Cline Trucking of Tonopah, from 1955-1957. Hauled ore to the Stevens Mill in Austin, Nevada.
2. George Rong, Manhatten, Nevada; Hoistman for the Great Western Mining Company (deceased).
3. Norman Coombs, Tonopah, Nevada; Legal Represenative in Nevada for the Nevada Antimony Company.
4. James Larson, Tonopah, Nevada; Truck Driver for Nevada Antimony and later for the Great Western Mining Company.
5. Rudy Rundberg, Austin, Nevada; Associate of Vollmar and Noack. Operated the Clifton Mill for Stevens.
6. Hugh Cameron, Reno, Nevada; Nephew of Vollmar, worked at the mines (1939-1942) during summer vacations from High School. States "ore production during this time was much higher than the State reports".
7. Pat Stevens, Austin, Nevada; Wife of Ted Stevens; (mill owner and operator of Stevens Mill, Austin, Nevada).
8. "Gab" Nagy, Austin, Nevada; Miner for Vollmar, 1939-1942; Mill operator for Ted Stevens 1955-1968.
9. Don Cirac, Kingstone Village, Nevada; Leasee of the White Caps Mine, Manhatten, Nevada, 1953-1956.
10. Bob Wilson, Round Mountain, Nevada; Miner at Round Mountain, 1955 - present.
11. Jack Swanson, Gabbs, Nevada; Miner for the Last Chance Mining Company 1948 and again from November, 1952 through May, 1953; when the mine shut down.
12. Carl "Skook" Berg, Round Mountain, Nevada; Born and raised in the area, familiar with past mining operations in the area.
13. Rene Zaval, Round Mountain, Nevada; Old time resident of the area. Friend of Vollmar.
14. Frank Brotherton, Tonopah, Nevada; Miner for the Last Chance Mining Company 1952-1953 (deceased).
15. Bob Cornell, Gabbs, Nevada; Sank well on the property (1950) for the Last Chance Mining Company.
16. Tom Cahill, Gabbs, Nevada; Born and raised in Round Mountain. Worked at the mine in 1950 for the Last Chance Mining Company.
17. Alan Aric, Pasadena, California; Persident of Nevada Antimony Corporation, after the death of the previous president; George Olivier.

SAMINCORP
SOUTH AMERICAN MINERALS & MERCHANDISE CORPORATION
425 PARK AVENUE
NEW YORK 22, N. Y.

TELEPHONE MURRAY HILL 8-4100
CABLE ADDRESS: SAMINCORP, NEW YORK

PURCHASE CONTRACT NO. 1052-P

August 5, 1958

Great Western Mining Company
P. O. Box 727
Central Valley, California

Attention: Mr. George A. Sturm, Partner

Gentlemen:

Referring to our various conversations, we confirm our purchase from you of the below-mentioned material at the following terms and conditions:

I QUANTITY : Approximately 46,000 pounds net wet weight.

II QUALITY : Antimony Concentrates as produced by you at your mine in Nevada, assaying approximately as follows:

Antimony	67%
Sulphur	28%
Silica	2.6%
Iron	1.9%
Lime	0.2%
Arsenic	0.06%
Copper	0.02%
Lead & Zinc	Traces
Silver	About 0.40 ounces per short ton
Gold	About 0.03 ounces per short ton

III PACKING : In bags suitable for export shipment.

IV SHIPPING SCHEDULE : We understand that the material is available for prompt shipment from Nevada to San Francisco. Please await our shipping instructions, which will follow shortly.

V DELIVERY : FAS San Francisco, with all charges up to free-alongside-steamer, including wharfage and handling, if any, being for your account.

VI PRICE : $2.25 per unit of antimony content and per short ton of 2000 pounds net dry weight. This price is subject to a sales commissior of 5%.

VII PAYMENT : (a) 90% against the following documents:

1. Your invoice in triplicate
2. Clean, signed, negotiable dock receipt, issued in accordance with our instructions, and evidencing delivery to "free-alongs steamer San Francisco"
3. Weight certificate listing gross, tare, and net weights for tl entire shipment and bag per bag.
4. Provisional assay certificate.

Ret'd to Mr. Buchnier

The Nevada Antimony Company
Los Angeles, California

Gentlemen:

Re: Mining Claims of The Nevada Antimony Company
Located in Township 10, North Range 42 East.
Nye County, Nevada. Elevation 8,100 feet.

Property: Consists of fifteen claims held by possessory title.

Topography: The dominant features of the topography are long, rather narrow, flat-topped ridges which have a northwesterly trend. The country is drained to the southeast by rather narrow flat draws.

Geology: The rocks of the district are of many kinds and occur in complex association. They have been formed in part by deposition beneath the sea and in part by intrusion as igneous masses, as well as eruption of volcanoes. All of them except the largest have been metamorphosed more or less. The bedrock series consists of sedimentary rocks which were turned into a nearly vertical position during the post-Jurassic deformation. These rocks represent beds of clay which have hardened and metamorphosed. Interpolated in these sediments are layers of metamorphic lavas and tuffa, showing the volcanic eruptions occured while the sediments were being deposited. Irregularly intruding the sedimentary rocks with their included volcanic layers are masses and dykes of various granular igneous rocks, such as granite and gabbro. Clay sites and schists predominate, the latter produced by metamorphism of both ancient sediments and igneous rocks.

Local Geology: An irregular isolated area of Ryolite porphyry in shape Approximately one mile across, was intruded as a batholith into the formation about the time of the great post-Jurassic upheavel. This was accompanied by fissuring, faulting, and shear-zoning. It is reasonably certain that the mineral bearing veins of this section were also

formed shortly after that time, and that their age is early Cretacious.

The vein system consists of a series of sheeted zones containing several known veins, the main lode having a strike north and south with a dip of approximately 75 degrees to the east and three veins with a strike east and west, the later being cutter veins. The veins were formed chiefly by replacement along these zones and in instances have all the characteristics of true fissure veins. These sheeted zones were the openings which afforded channels for the ascending waters. The main vein, wherever exposed, shows approximately three feet of dolomite, some quartz porphyry with three feet of almost pure antimony ore against a grano-diorite foot wall.

The antimony occurs in lenses or short shoots, but has been opened up with cuts and shallow shaftsfor a distance of approximately 1500 feet along the vein. The vein-filling along the sides of the antimony all carries a small amount of gold values.

Conclusion: In conclusion, I will say that the showing and possibilities are so impressive that I feel confident, with a reasonable amount of money expended, that this mine will rank with the big producers of the country.

The writer's observations were made from rocks wherever exposed, and from information gleaned from old-time miners in the district.

Respectfully submitted,

(Signed) W. H. Gardner

COPY OF REPORT ON THE

NEVADA ANTIMONY PROPERTY

NYE COUNTY, NEVADA.

INTRODUCTION

Following correspondence with Burton H. Buehner of Los Angeles, and after reading a report by W. H. Gardner, which contained some very flattering statements concerning the property the writer examined the workings in a snow storm, under very unfavorable circumstances for the inspection of the surface rocks and outcrops, which were mostly covered by snow.

The following report, therefore, deals chiefly with those workings which were visited on February 23, 1935., the trip being covered in about fourteen hours from Tonopah.

LOCATION

The property of the Nevada Antimony Company is situated in Township 10 North, Range 42 east, Nye County, Nevada., approximatel7 56 miles due north of Tonopah, from which it is reached by auto road in about two hours.

It is 12 miles due west of Round Mountain Mining District.

There are fifteen unpatented claims in the group, which is located generally on the Index Map.

PHYSICAL FEATURES

The claims are spread over the high ridges and upland valleys and gulches of the Toyabe Range. They are reached through Wall Canyon which penetrates the abrupt scarp and eastern flank of the range, where the elevation changes from 5800 feet in the Big Smoky Valley to over 8000 feet in six miles, over a fair auto road. The Canyon walls are not steep and the road not difficult of maintenance.

There is an abundance of stunted forest growth for fuel and mine timber purposes on the property, and on adjoining government land.

Water is scarce, the nearby source of domestic water at present being confined to a very small dripping spring.

Plate 1 shows the location of a small log cabin on the property, which is new and in good condition. Another boarded cabin, containing sacked ore is shown on the Last Chance Claim. A fair road connects these two cabins, which will provide transportation facilities for the haulage of ore from the Last Chance Claim to the lower cabin and auto road.

GEOLOGY

The entire surface of the claims, with a few notable exceptions where some observations were made, was snow covered at the time of the writer's visit. Examination of the various tunnels disclosed ancient Gneisses and Schists. More recent sediments in the form of shale beds dipping locally in a steep angle to the west, and striking northwest, a prominent outcrop of felsitic porphyry, showing inclusions of Domomite, and portions of what appears to be a large dyke of recent Rhyolite.

The presence of all these rocks within a small group of claims is perhaps typical of Nevada mountain ranges, at least of those which the writer has seen. This condition naturally suggests interesting speculations but on account of the snow covering

no effort was made to correlate or classify these rocks. A few observations in connection with the occurance of veins and ore bodies within these rocks are given, however, in the following:

VEINS AND ORE DEPOSITS

1. Within highly metamorphosed rocks, gneissic in appearance, the writer observed a small quartz vein in the tunnel on Grouse Spring #4 claim. 18 inches of vein material near a fault cut off assayed only traces of gold and silver. However, a sample was taken in the face of the tunnel, where veinlets of quartz were exposed, which assayed 0.5% antimony. This is an interesting fact which may indicate the wide spread presence of antimony in the vicinity. See plate 3.

2. Disclosed in a tunnel on Silver Martin #2 claim (plate 2) are several mineralized fissures showing evidence of strike faulting. Two samples taken there assayed only traces of gold and silver.

3. The tunnel on Last Chance claim, where an ore house is built on the dump, has been recently extended to a point under a small deposit of almost pure stibnite, (antimony trisulphide, when pure carrying 71.4% antimony) (Sb_2S_3) which was discovered on the surface. Near the portal of this tunnel, the shale beds are fissured, folded, and distorted by movements of considerable proportions. Dolomitic shale and limestone were observed, also other evidence of the proximity of igneous rooks on the surface, and the writer is of the belief that the massive stibnite boulders, which show no vein structure alignment or banding of other minerals, represent a replacement of portions of favorable beds of shattered, limy and dolomitic shale, near a contact of igneous rocks.

Plate 2 shows details of this fissuring and deposit. At the time of the writer's visit the boulders of almost pure stibnite, slightly oxidized where surface waters had penetrated cracks, were seen in the bottom of the tunnel and in a small crosscut off the tunnel near the face. A sample of the sacked ore, about ten tons, in the ore house on the dump of this tunnel, assayed 53% antimony.

Shafts and pits on the Last Chance claim, east of the tunnel just described, were seen, but not mapped because filled with snow. It is said that antimony ore of considerable quantity was taken from these also.

4. Rocks containing antimony were seen on the dumps of shaft and pits on the Grouse Springs #3 claim, in the workings of which was disclosed veinlets of quartz in a fissure zone.

In general, the fissures mapped were small and of little prospective value, with the exception of the deposit on Last Chance claim. The strike of the fissuring is seen to be generally East-West.

No observations were made which would indicate a large vein structure, although a contact along the porphyry or ryolite dykes might constitute such a structure. zone

Sufficient observations to determine continuous outcrop of veins or dykes were impossible, and the writer leaves this section of the report in an unfinished condition, to be completed, if feasible, later.

HISTORY AND PRODUCTION

It is doubtful if the production of ore of any kind was made from this group of claims. Some antimony may have been shipped during high prices, but the amount, from the evidence seen in the workings was necessarily small.

The claims are not far from Round Mountain and Manhattan and would have been thoroughly prospected for silver and gold possibilities many years past. However, there is here a new development, which is neither barren nor uninteresting. The high price of antimony now (14½ ¢ per pound) should provide sufficient inducement and ample remuneration for the high grade ore, such as is seen in the Last Chance tunnel.

CONCLUSIONS

1. Further work at present should be confined to the recovery of the massive stibnite ore, wherever available, and development of a limited character along the fissures which haveproduced this type of ore in the shale beds. Further recommendations may be possible from reports of progress.

2. The marketing of antimony ores is of such a nature and the price so erratic that any large investment, in a mill, for example, would be a very doubtful venture, unless the product could be carried through to the metal itself. Such a plan, however, would depend entirely on the development of a large tonnage of profitable milling ore.

3. Further expenditure of funds for more claims, except as a means to obtain water is unwarranted. Careful inspection of the surface after the snow melts would probably result in the relinquishment of some of the claims in the group.

4. Gold and silver prospects on these claims have not been disclosed to the writer, though prospecting near the contacts of igneous rocks may prove these rare metals to be present also. No attention should be paid to theories about the favorable possibilities unless there is evidence that gold and silver do exist in the veins now uncovered. Outcrops should receive enough inspection and sampling to prove these points.

5. More water is needed if development requires a larger camp or power application.

6. Very little expense is necessary in order to maintain a good road for haulage.

7. Ore can be hauled to the railroad at or near Tonopah for about $5 per ton.

8. No ore reserve figure can be given, due to the nature of the deposit and of the development. About ten tons of high grade antimony ore is sacked ready for shipment.

9. Workings visited are generally in good condition, indicating that extensive timbering would be unnecessary.

10. The tunnel on the Last Chance claim shows rock alteration which is due to the percolation of mineralizing solutions, from which the massive stibnite boulders were deposited.

GEOLOGIC MAP OF THE LAST CHANCE MINE

NYE COUNTY, NEVADA

NEVADA ANTIMONY CORP.
ALAN ARIC: PRESIDENT

LAST CHANCE, Antimony Mine

AKA, Silver Divide, Bastian, Wall Canyon, Herd, Francisco (?), Located in Section 17 (projected), T. 10 N., R. 42 E., on base map, U.S. 1:25,000 scale topographic map, Tonopah sheet, in Nye County, Nevada (county seat, Tonopah).

Subject mine is composed of 15 lode mining claims situated in the Jett District on the divide between Wall Canyon and San Pablo Canyon on the east flank of the Toiyable Range at an elevation of approximately 8000' and is connected by a dirt road approximately 11 miles long running westerly from Nevada State Highway 8A, said dirt road intersects Highway 8A at a point approximately $5\frac{1}{2}$ miles south of the intersection with State Highway 70 running easterly to Round Mountain. The intersection of State Highway 8A and 70 lies 63 miles south of Austin and 151 miles south of Battle Mountain and 54 miles north of Tonopah.

EXHIBITS ATTACHED

1. GEOLOGIC MAP, from Nevada Bureau of Mines Bulletin 61, Plate 8. Shows a portion of the Western Workings and the Eastern Workings. The Mill has been dismantled and only a portion of the foundation remains. A portion of the Mill building remains with its foundation. The Ore bin just south of the Main Shaft, Western Workings, is in fair condition.

2. CLAIM MAP, provided by mine owner. Shows Main Shaft, Western Workings located on the La Castana Claim, the Eastern Workings and three 40' deep shafts on the Santa Gertrudes Claim, and the Old Tunnel on the San Geronimo Claim.

3. MINE MAP, Last Chance Mine, composite map by Western Research + Engineering Co., data from various sources, shows #1 Tunnel, #2 Tunnel, Main Shaft, 15'-, 60'-, 140'- and 185'- levels of Western Workings.

4. REPORT on Last Chance Mine, from Nevada Bureau of Mines, Bulletin 61, Plate 8, Antimony Deposits of Nevada, pp. 140, 141.

5. Copy of REPORT on "Nevada Antimony Property" by Wm. A. O'Kelly, formerly Chief Engineer for Anaconda Butte operations.

SAMPLE LOCATION

ULTRAMAFIC INVESTIGATION

1. Big Horn No. 1; Ore stockpile material
2. Big Horn No. 10; Yellow Post opencut material
3. Big Horn No. 14; West end of claim; small pit material
4. Big Horn NO. 7; Big Blue shaft material
5. Big Horn No. 7; Big Blue tunnel dump stockpile
6. Big Horn No. 1; curve in road south of dozer cut
7. Wall Canyon No. 91 (?); north side of road, small opencut
8. Big Horn No. 10; resample of 2.
9. Big Horn No. 10; NW corner area; random rock sample, float
10. Big Horn No. 10; Crest of ridge; green prospect
11. Wall Canyon No. 58 (?) North side of road; Deer Location
12. Wall Canyon No. 57 (?); North side of road; Slide area & outcroppings
13. Wall Canyon No. 56 (?): North side of road; rectangler grren
14. Big Horn No. 10; Between sample No. 9 & No. 10; black silicious (?) outcropping
15. Big Horn No. 14; resample of 3
16. Big Horn No. 12; SE end; top of hill
17. Big Horn No. 1; NW of sample 6 (about 200 ft.)
18. Big Horn No. 2; above dozer cut
19. Big Horn No. 1; Near north center side line; "Moms' Dike"
20. Big Horn No. 1, South end of the generator Building
21. Explore; lower granitic Porphyry (?)

22. Explore; upper granitic prophyry dike

23. Big Horn No. 15; near corner No. 1; road material

24. Between sample 13 and road side; to the west

25. Location area of Big Horn No. 19

26. 100 feet north (approx.) from location; Big Horn No. 19; open cut in draw

27. 150 ft. northeast of Big Horn No. 10 Location; opencut material

28. Big Horn No. 16; Post No. 2 (SW corner) area

29. East slope of hill across from sample 2 SE)

30. Big Horn No. 14; shafts & pits, north of Location

31. Big Horn No. 14; going south from location along outcroppings.

32. Twin Road intersection; to the west of sample 7

33. From sample 7; along along hillside to side road; sample 24 area.

34. Plug outcroppings

35. Explore; just between volcanics; south of the flat ridge incline shaft.

36.

IN REPLY
REFER TO:

August 6, 1984

Dear Gerry:

Herewith is a copy of our bulk mineralogy (X-ray diffraction analysis) summary of your suite of samples from the Wall Canyon Mine area.

My schedule this summer will not bring me to the Big Smoky Valley area, but I will contact you the first time I can visit the Round Mountain area.

Best regards,

Barney Poole

Enclosure

copy to Gerry Doyle

Wall Canyon Mine area, Toiyabe Range, NV

#5 - Dump Stockpile
qz., dolo., serp., illite
quartz, dolomite, serpentine, illite

#19 - qz, dolo., magnesite, serp

#10 - dolo., qz, illite

#5 - 400' South and a little east - dolo., qz

#3 - dolo., qz., calcite

#23 - dolo., qz, magnesite, trace of serp.

B. Poole

(Gerry Doyle samples)
P.O. Box 4
Round Mountain, NV 89045

Comments

- alluvium [illegible] shales fragments
- oxide zone
- sulfide (unoxidized) minor pyrite only
- oxidized zone (fault?) moderate water flow
- unoxidized tuff with minor pyrite, chlorite common
- Calcite vein
- Yellow heavy minerals (realgar?) [illegible] yellow
- Silica & pyrite veins ~ 1% pyrite
- 1-2% magnetite, minor pyrite, strongly silicified, chlorite common

Drill hole attempted to penetrate volcanic cover to test underlying sediments → sediments not encountered

Comments

Orange to grey thin bedded Calcareous shale

upper portion of dike Have been strongly infiltrated by calcite

Qtz monzonite porphyry minor sulfides Fresh Biotite

oxide / sulfide

Breccia zone with pyrite

thin bedded black lime 1% pyrite

Grey to black slatey shale with significant secondary Calcite Qtz & Pyrite veins ~ .5–1% pyrite

Black to green black Jasperoid – Extensive secondary qtz-pyrite veining ~1–3% pyrite

Comments:

evident sulfide

relatively unaltered Dike – partly chloritized, silicified. Biotite is fresh. Dike has been fairly strongly invaded by calcite.

Thin bedded black limestone

Black thin bedded limey shale with variable calcite content. Pyrite varies from .5–4%.

Comments

- 0–~75 ft: oxide; ~75 ft: sulfide
- 0–~100 ft: Strongly silicified, minor qtz pyrite veins common
- ~100–~135 ft: 2–10% / 1–10% pyrite; silicified – calcite veins
- ~135–~160 ft: weakly silicified minor pyrite
- ~160–~200 ft: weakly calcareous no pyrite (Possibly same or similar unit to Hole WC #14)
- ~200–305 ft: minor pyrite increasing toward bottom of hole
- ~300–305 ft: silicified

Grey limestone
minor qtz veining

Blackish limestone with minor qtz veining & minor pyrite
more plating

Emerald GREEN mineral present unknown chemistry

more qtz 1-5% veins .5-2% pyrite

whitish grey Jasperoid 1-2% pyrite

Pyrite vein

Grey to Black Jasperoid with Extensive secondary qtz veining 1-5% pyrite

white Rhyolite Dike with .5-1% pyrite

Jasperoid with olive green cast in color
extensive secondary qtz veining
.5-2% pyrite

Comments

oxidized limey shale (orange)

Fault

unoxidized grey shale - minor sulfides. Fairly strongly silicified

Grey limey shale strongly veined by small white calcite veins - .1-.2% sulfides

Black shale minor secondary calcite veins. Minor sulfides

Grey shaley limestone - strongly silicified in part - numerous secondary calcite veins - minor sulfides

Comments

Copper oxides PRESENT IN OXIDE PORTION

oxide

sulfide

Grey Thin Bedded limestone. Strongly oxidize to gossan at surface very finely disseminated sulfides .5-1%

Zone of Qtz + minor calcite veining (?)

Black Limey Shale with Extensive sulfides up to 5% (Pyrite) Some Silicification

calcite-qtz vein

Dark grey Lime possibly Transitional from above. Numerous secondary calcite veins = qtz. minor sulfides in this portion of hole.

Comments

oxide
sulfide

Possibly upper plate rocks of the Vinini formation. Unit appears highly contorted

strong water flow ~ 50 gallons/minute

Partially silicified Light grey ~~limestone~~. Pyrite content ~ 2% at top of unit decreases to ~ 2% at bottom silicification increases toward base of unit.

Black to dark grey thin Bedded Calcareous Shale. Numerous secondary qtz/calcite veins. Pyrite content varies between 1-3%.

Water flow at bottom of hole very strong ~ 160 gallon/minute (150)

Mining Districts

MINING DISTRICTS

STARTING AT THE LANDER-NYE COUNTY LINE, AND CONTINUING ALONG THE EAST SIDE OF THE TOIYABE MOUNTAIN RANGE. THE MINING DISTRICTS WITHIN SMOKEY VALLEY ARE:

1. BLUE SPRINGS MINING DISTRICT

ORGANIZED: 1892

AREA: EXTENDS FROM THE LANDER-NYE COUNTY LINE TO CLEVELAND CANYON AND INCLUDES BROTHERS WATER CANYON; WHICH IS THE NORTHWEST FORK OF PARKS CANYON. INCLUDES BOWMAN,AIKEN,DECKER,ALICE GENDTON,DECKER BOB,McLEOD,GREENHALGH,TRAIL,CLEVELAND, AND BROTHERS WATER CANYONS.

2. MILLETT MINING DISTRICT

ORGANIZED: 1904

AREA: REMOVED FROM THE TWIN RIVER MINING DISTRICT THE AREA OF PARKS, WILDCAT, CLAY, MOES, AND MICHELS CANYONS.

3. TWIN RIVER MINING DISTRICT

ORGANIZED: 1864

AREA: FROM PARKS CANYON ON THE NORTH, INCLUDED ALL OF THE LATER MILLETT MINING DISTRICT, AND CONTINUES SOUTH THROUGH SUMMIT, WISCONSIN, OPHIR, LAST CHANCE, HERCULES, NORTH TWIN RIVER, SOUTH TWIN RIVER, BELCHER, AND COVE CANYONS.

4. JETT MINING DISTRICT

ORGANIZED: 1876

AREA: THE DRAINAGE OF JETT AND BROAD CANYONS.

5. ANTELOPE MINING DISTRICT

ORGANIZED: 1881

AREA: PABLO, WALL, AND ANTELOPE CANYONS

6. TOYABE MINING DISTRICT

ORGANIZED: 1878

AREA: BOYD AND WOODS CANYONS

7. PEAVINE MINING DISTRICT

ORGANIZED: 1906

AREA: ALL OF THE PEAVINE DRAINAGE AND THE HEADWATERS OF THE REESE RIVER; AS FAR WEST AS POPULAR CREEK (NOW CALLED BEASON CREEK).

(234) Item 10

PROPERTY NAME: Last Chance Mine
OTHER NAMES: Big Horn Antimony Mine
MINERAL COMMODITY(IES): Antimony, silver
TYPE OF DEPOSIT: Vein, Sheer zone
ACCESSIBILITY: Via dirt road up Wall Canyon
OWNERSHIP: Gerald Doyle, Dale Clouser, 1983
PRODUCTION: 192 tons antimony metal through 1963 (Lawrence, 1963)
HISTORY: Discovered in 1915, produced during WWI, WW II, 1947-55, 1957-58

County: Nye
Mining District: Jett
AMS Sheet: Tonopah
Quad Sheet: Toms Canyon
Sec. Unsur, T _____, R _____
Coordinate (UTM):
North 4,285,160 m
East 0,475,000 m
Zone +11

DEVELOPMENT: Vertical shaft, lower intersecting adit, cuts, trenches

ACTIVITY AT TIME OF EXAMINATION: None, but property has been drilled within the past one or two years, ue fresh trenching done and two old portals have been cleaned and reopened, probably this year)85).

GEOLOGY: Recent work above and east of the old main shaft exposes a N55W, NE-dipping quartz-carbonate vein. Vein material is streaked green from copper probably from oxidizing t tetrahedrite. Dark sulfide (tetrahedrite?) disseminated throughout the vein outcrop. Ore specimens collected on the dumps near the main shaft consist of massive stibnite with white quartz, calcite and fragments of black carbonaceous shale. Wall rock of the vein is carbonaceous shale and limestone.

Sample sites 2688, 2689

REMARKS: Exposures at the main portal are not good, outcrop at sample site 2688 may, however be the principle structure.

(234) Item 11

PROPERTY NAME: Big Horn #7 Claim
OTHER NAMES: Last Chance Mine
MINERAL COMMODITY(IES): Antimony
TYPE OF DEPOSIT: Vein, shear zone
ACCESSIBILITY: Via 4WD road from L.C. mine
OWNERSHIP: Gerald Doyle, Dale Clouser, 1983
PRODUCTION: Unknown
HISTORY: Unknown

County: Nye
Mining District: Jett
AMS Sheet: Tonopah
Quad Sheet: Toms Canyon
Sec. Unsur, T _____, R _____

Coordinate (UTM):
North 4 1 2 8 5 3 6 0 m
East 0 4 7 4 6 8 0 m
Zone +11

DEVELOPMENT: One adit

ACTIVITY AT TIME OF EXAMINATION: None, but adit has been recently cleaned out and retimbered at portal, drilling in area within past year or two.

GEOLOGY: A N60-65E, 50SW-trending fault zone is exposed at the portal of the adit, wall rock here is a rubble of black, carbonaceous shale, limestone, and chert cemented with orange and orange-brown iron oxides. Blocks of rhyolite dike are found in the colluvium above the portal, possibly the dike follows the fault zone. Vein material collected from the dump consists of clots and disseminations of stibnite in white quartz with calcite, iron and antimony oxides, pale blue-green oxide mineral stains the quartz-possibly indicates the presence of tetrahedrite.

Dear Mr. Doyle:

The plan for dewatering the C-100 level adit as outlined in the enclosed environmental assessment is hereby approved. This is an approval of your operating plan 04/86/005. It is unnecessary to resubmit an operating plan each year for items approved in a previous plan. We do appreciate being informed of your progress.

If I or my staff can be of further assistance don't hesitate to call.

Sincerely,

Guy W. Pence

Decision Notice, Environmental Assessment
and
Finding of No Significant Impact
for
Operating Plan #04-86-005
Gerald Doyle-Wall Canyon

Decision Notice

It is my decision to approve Operating Plan 04-86-005 submitted by Gerald Doyle for his claims in Wall Canyon. These claims are in Sections 16 through 22, and Sections 28 through 30, T. 10N., R. 42E. MDM in Nye County Nevada. All but one item had been approved on May 6, 1985 under last year's operating plan. The item not previously approved but approved in this operating plan called for building a reservoir to temporarily store water from the central addit which must be dewatered to allow sampling. The alternative approved for this purpose is (D) to build a reservoir on previously disturbed land immediately adjacent to the addit. Water will be allowed to percolate and evaporate from this impoundment. Alternatives to this were A, no action; B, build a dam in the canyon below the addit; C, pump to the opposite side of the mountain and allow the water to run off overland.

My decision is based on minimizing resource disturbance, ease of reclamation, economic considerations for the operator and feasibility.

Environmental Assessment

Gerald Doyle submitted operating plan 04-86-005. All but one item had been approved in FY 85. Mr. Doyle needs to dewater the central addit on his claim group in order to sample that addit. Water samples provided to Harry Van Drielan of the Nevada EPA indicate low toxicity and near neutral pH. Mr. Van Drielan's comments are in Appendix A.

Originally Mr. Doyle wanted to place an impoundment in the Canyon below (in elevation) and north of the addit or to pump the water over the ridge southwest of the addit and allow it to flow overland. On November 16, 1985 Mr. Doyle and Bud Henderson met on the site to determine the best alternative. The alternatives considered and the mental evaluation done are summarized in the following paragraphs

Alternative A is the No Action Alternative. Mining laws and Forest Service Policy based on those laws guarantee reasonable access to mineral operators for the purpose of discovery and development of the mineral resource. Though a No Action Alternative is required under N.E.P.A., it would be unreasonable to expect an operator to explore an addit without first removing the water.

Alternative B calls for building a dam in the narrow canyon below the addit. The canyon is relatively steep (between 10% and 30% slopes) with steep canyon walls. The soil is moderately to extremely erodable. A previously undisturbed area would require extreme modification. The dam would need to be relatively high and thick to provide for safety. Since the canyon is fairly steep the impoundment would be larger than one located on flat ground. Construction cost and reclamation cost would be high relative to other options.

Alternative C, pumping water over the ridge would probably be about as expensive as Alternative B due to pumping station costs, deenergizing structure cost and reclamation of deenergizing structures and erosion which would occur in spite of reducing the head produced by the water.

Alternative D, the preferred alternative involves cutting down a previously disturbed somewhat flattened area immediately adjacent to the addit. The cut material will be used as fill for making the impoundment walls. Though the impoundment is calculated to be 3 feet in height, the walls will be built 5 feet high to provide an ample safety margin. The earthen dam will be 8 to 10 feet wide at the top with interior and exterior walls of 45° or less. Since this area is disturbed and flattened under previous operations no additional reclamation costs are expected. The existing bond will cover the operation. Equipment operation will be easier relative to down canyon operation and consequently should be considerably cheaper. The water will be allowed to percolate and evaporate from the pond after sampling.

The following table indicates subjective values on a scale of 0 through 10 with 0 being the worst situation and 10 the best.

Subjective Comparison

	A No Action	B Canyon Dam	C Overland Flow	D Evaporation Pond
Resource Disturbance	10 None	3	5	8
Reclamation	10	2	6	10
Operator Ecomomics	0	4	4	9
Feasibility	0	8	8	10

There should be no additional resource disturbance under Alternative A, but much under Alternative B due to where the dam is to be placed and the probable engineering specifications necessary to assure an adequate margin of safety. The overland flow Alternative would cause less disturbance than Alternative B but more than Alternative D because deenergizing structures would reduce but not completely eliminate the destructive potential of flowing water. Alternative D will take place on previously disturbed ground. Little additional disturbance should occur.

Reclamation for Alternative A and D will be essentially the same, as the existing disturbance will be reclaimed and little if any additional area will be disturbed with either Alternative.

Building and reclaiming an impoundment in the canyon as in Alternative B will be more difficult and expensive than building the impoundment near the addit as in Alternative D. Alternative C would be expensive due to the length of pipe and pumping substations as well as the need to haul heavy rocks and gabions to build deenergizing structures. No Action would not allow the operator to meet his objectives.

No action is infeasible because the operator could not sample the addit without dewatering it first. Alternatives B and C are about equally feasible. They could be done but more engineering expertise and care would be necessary to insure success than Alternative D. Alternative D is most feasible as it can be done without disturbing new ground, without moving water very far or exposing areas to the cutting action of moving water.

Finding of No Significant Impact

I have determined that this action would not significantly affect the quality of the human environment. Therefore an Environmental Impact Statement is not needed. This determination was made considering the following factors:

A. The irreversable and irretrievable resource commitments and adverse cumulative and secondary effects associated with this project are minor.

B. The physical and biological effects are limited to the area of planned development and use.

C. No known threatened or endangered plants or animals are within the affected area.

This decision may be implemented immediately. It is subject to appeal pursuant to Secretary of Agriculture Appeal Regulations 36 CFR 211.18, except for the mining operator who can appeal pursuant to 36 CFR 228.14.

A Notice of Appeal filed under 36 CFR 211.18 must be filed with this office within 45 days from the date of this decision. A Notice of Appeal filed pursuant to 36 CFR 228.14 must be filed with this office within 30 days from the date of this decision.

APPENDIX A HARRY VAN DRIELAN

Re: Big Horn Mine

Greetings:

I have received and reviewed your submittal for the proposed dewatering of the mine. The hydrogen ion activities (pH) you report indicate that surface water in this region is more acidic than the waters taken from the mine. By inference, it is expected that the toxic metal burden in the impoundment of the mine waters will be very light and that this water should pose little or no endangerment to the animals and plants in the area. It is recommended that the impoundment is sized to hold the total amount of water pumped from the mine and that the bottom of the impoundment allows for a large amount of percolation. Upon completion of bulk sampling and cessation of dewatering, the impounded water should be allowed to percolate and evaporate; when standing water is no longer visible the dike or dam must be breached to allow free drainage of rain or snow-melt runoff.

Enclosed are the maps of the mine you sent. These are felt to be more valuable to your prospects than are useful to keep in the file. It is requested that you provide a 7-1/2 minute topographic map or an orthophoto quad, marking the mine adit and the impoundment.

Should you have any question in this matter, please ask.

Respectfully,

Harry van Drielan

WALL CANYON-PABLO CANYON WATER SAMPLES

The following water samples were secured from their respective locations on July 14, 1985.

Each sample contained approx. 1/2 quart of water. The samples were placed in clean jars with sealed lids.

The samples were taken to the assay laboratory at Smoky Valley Mining, and tested by titration to determine the Ph of each sample. The samples were tested with 24 hours of their being secured.

The following results were recorded:

SAMPLE #1. WC-1 Ph = 8.13 Location: C-100 Adit: Central Workings.

SAMPLE #2. WC-2 Ph = 7.81 Location: Spring below proposed dam site.

SAMPLE #3. WC-3 Ph = 8.10 Location: Pablo Creek at Mine Canyon Road.

SAMPLE #4. WC-4 Ph = 8.31 Location: West Adit West Workings.

SAMPLE #5. WC-5 Ph = 8.05 Location: Adit Level; East Workings.

Sample $6. WC-6 Ph = 7.64 Location: Spring avove house in Wall Canyon.

Januray 28, 1986

Mr. Gerald Doyle
Box 4
Round Mountain, Nevada 89045

Dear Mr. Doyle:

Mr. Garcia asked me to write to you concerning the Wall Canyon Road. Enclosed please find a copy of a map of that road. I have marked the area Nye County blades in green.

The road in this area is bladed about once a year.

Our motor grader is now in the Mores Creek Area. As soon as the roads in that area are completed we will be moving down the valley. At that time we will blade the road in the Wall Canyon Area. If you wish to talk to me concerning the Wall Canyon Road please feel free to call me at 482-3335.

Sincerely yours,

Phyllis Logan

PROOF OF PERFORMANCE AND COMPLETION OF

ANNUAL ASSESSMENT WORK

STATE OF NEVADA:
:SS
COUNTY OF NYE :

The undersigned in whose behalf the following work was performed or improvements made, certifies that at least $13,000.00 dollars was expended and/or the following labor expended or improvements made having a value thereof, consisting of:

1. Completing the reopening and timbering of the C-100 level from the Main Shaft to the Portal.
2. Roadwork on the Big Horn No's 1,4,7,9,11,14,20; and the WC No's 3,7,8,10,32,34,35,36,38,39,41,54, 55,57,91,103, & 104 & on the Main Mine Road in Wall Canyon.
3. Layed track on level C-100 from the Main Shaft to the Portal.
4. Erected electrical lines on level C-100 from the Main Shaft to the generator.
5. Installed a main electrical switch box and circuit breaker on level C-100.
6. Installed a pump & pipe lines from level C-140 to level C-100.
7. Constructed a Mine Water Retaining Dam and rerouted the mine roads around the dam area.
8. Worked at upgrading the mine to conform to MSHA Standards.
9. Worked on rehabiliting the Hoist House, Generator Building, & Foremans' House.
10. Built a gate & fence on the Main Mine Road approx. 3/4 mile from the Summit of Wall Canyon.

All of the work done was done for the benefit of all of the Lode Mining Claims of the Big Horn and WC Claim Groups. These claim groups are contiguous. The names of the individual claims and their related information is listed in Exhibit "A"; which is attached hereto. All of these claims are Lode Mining Claims and are not patented.

These Lode Mining Claims are located in Sections: 17,18,19,20,21,29, & 30: Township 10 North: Range 42 East: MDM & B, situated in the Antelope Mining District (Organized in 1881); of the County of Nye, State of Nevada, during the year ending 12:00 Noon, September 1, 1986.

The Claim Maps are filed as Documents No's: 25401, 37401, 46999, 93614, & 101454 in the Nye County Recorders Office.

The work described above was performed by Gerald A. Doyle and Janet B. Doyle and/or their Agents. The above cited work is ongoing.

The names and addresses of the Owners are: Gerald A. and Janet B. Doyle, P. O. Box 450, Round Mountain, Nevada 89045.

Such expenitures were made by and at the expense of Gerald A. Doyle and Janet B. Doyle; owners of said claims for the purpose of holding said claims for the valuable minerals contained therein.

Gerald A. Doyle
